## Preface

One of the most significant contributions of The DHS Program is the creation of an internationally comparable body of data on the demographic and health characteristics of populations in developing countries.

The DHS *Comparative Reports* series examines these data across countries in a comparative framework. The DHS *Analytical Studies* series focuses on specific topics. The principal objectives of both series are to provide information for policy formulation at the international level and to examine individual country results in an international context. *Comparative Reports* are primarily descriptive, while *Analytical Studies* take a more analytical approach.

The *Comparative Reports* series covers a variable number of countries, depending on the availability of data sets. Where possible, data from previous DHS surveys are used to evaluate trends over time. Each report provides detailed tables and graphs organized by region. Survey-related issues such as questionnaire comparability, survey procedures, data quality, and methodological approaches are addressed as needed.

It is anticipated that the availability of comparable information for a large number of developing countries will enhance the understanding of analysts and policymakers regarding important issues in the fields of international population and health.

Sunita Kishor

Director, The DHS Program

## Executive Summary

International efforts, such as the FP2020 initiative, have focused renewed attention on family planning and necessitated standardized indicators of unmet need for family planning by which to measure progress. This study is the first publication specifically focusing on young women and applying the *revised* DHS algorithm for unmet need for family planning. This algorithm is fully comparable across countries and over time.

This study examines *current levels* and *trends* in unmet need among women between 15 and 24 years of age, both married and unmarried. It compares unmet need among different *age* groups. It explores *factors associated* with unmet need: place of residence, wealth, educational attainment, and parity. Finally, it describes levels and trends in the *components* of unmet need: age at marriage, fertility preferences, and use of contraception. The following are among the study's key findings.

### Unmet Need among Young Married Women

- Unmet need for family planning among young married women is highest in the West and Central Africa region (averaging 29.3%), followed by the East and Southern Africa region (25.5%); the region with the lowest level of unmet need is the Middle East and North Africa (10.8%). Among individual countries, unmet need is highest in Ghana (45.7%) and Haiti (44.8%) and lowest in Egypt (8.8%) and Indonesia (8.0%).
- Only slightly more than half (57.7%) of the total demand for family planning (unmet need plus current use of contraception) is satisfied in this population, on average.
- Total demand among young married women is highest in Latin America and the Caribbean (79.9%) and lowest in West and Central Africa (44.9%).
- Unmet need has declined among young married women in the majority of countries (51 of 61 countries). West and Central Africa is an exception; unmet need has increased in six countries in this region.
- Both total demand for family planning and the proportion of demand satisfied have generally increased over time among young married women.

### Unmet Need among Young Unmarried Women

- Unmet need for family planning is higher, on average, among young unmarried women than among young married women.
- Unmet need among young unmarried women is highest, around 40 percent, in the two African regions (41.7% in West and Central Africa; 39.8% in East and Southern Africa) Africa. Among individual countries, it is highest in Senegal (69.5%) and lowest in Ukraine (7.3%).
- Total demand for family planning among unmarried women age 15 to 24 is consistently high—about 90 percent in all the regions. By and large, young sexually active unmarried women typically do not want to become pregnant at the present time.

- What varies is the proportion of total demand that is satisfied. The proportion of demand satisfied ranges from 52.8% in West and Central Africa to 83.9% in Eastern Europe and Central Asia.
- Unmet need has decreased among young unmarried women in about half the countries in the study and increased or fluctuated over time in the remaining half. Increases in unmet need have occurred in the majority of countries in West and Central Africa. Demand for family planning has remained steady—and high—over time.

### **Number of Young Women with Unmet Need**

- An estimated 33 million women age 15-24 have an unmet need for family planning in the 61 countries included in the study. Nearly two-thirds—21 million—live in the 10 South and Southeast Asian countries. The remaining one-third of young women with unmet need (12 million) are distributed throughout the 51 other countries.
- There are more young married women than young unmarried women with unmet need for family planning in countries where this comparison can be made. This is despite the larger percentage of sexually active unmarried women with unmet need.

### **Age and Unmet Need**

- Among young married women, unmet need is highest among the youngest women (age 15-16) and declines with increasing age in most regions in the study.
- Young married women age 15-24 experience greater unmet need than do married women age 25-49 in all regions except the Middle East and North Africa (10.8% and 12.6%, respectively). The biggest difference in unmet need between younger and older women of reproductive age occurs in Latin America and the Caribbean (24.5% and 15.6%, respectively).

### **Factors Associated with Unmet Need**

- Unmet need is usually higher in rural areas for both married and unmarried young women. The exception is West and Central Africa, where unmet need among married women age 15-24 is significantly higher in urban areas than in rural areas in seven countries.
- Unmet need generally decreases as household wealth increases. In West and Central Africa, however, unmet need is also high for young married women in the richest wealth quintile.
- Unmet need declines with educational attainment in the Middle East and North Africa, Eastern Europe and Central Asia, South and Southeast Asia, and Latin America and the Caribbean. However, in Africa, unmet need increases with educational attainment in numerous countries.
- Unmet need increases markedly with parity. Differences are largest between young married women with no children and those with one child.

## Components of Unmet Need

- The proportion of women who are married by age 15 and by age 18 is highest in West and Central Africa (39.2% and 73.0%, respectively) and lowest in the Middle East and North Africa (13.4% and 48.8%, respectively) and Eastern Europe and Central Asia (6.1% and 39.4%, respectively). There is a general trend toward delaying marriage.
- The proportion of unmarried women age 15-24 who report they are sexually active is highest in West and Central Africa (18.8%) and lowest in East and Southern Africa (9.7%). Over time, the proportion who report they are sexually active declines in nearly as many countries as it increases (14 and 15 countries, respectively). It increases in all seven countries in Latin American and the Caribbean.
- Ideal number of children among young married women is highest in West and Central Africa (mean 5.5 children) and lowest in Latin America and the Caribbean (mean 2.4 children). Ideal number of children has increased in Eastern Europe and Central Asia (and selected West and Central African countries) while decreasing elsewhere, most notably in South and Southeast Asia.
- Ideal number of children is lower among young unmarried women than married women the same age in Africa and Eastern Europe and Central Asia. Ideal number of children has declined over time among young unmarried women.
- Most married women age 15-24 want to postpone a birth for two or more years. This preference has existed for some time and has become increasingly normative over time.
- A larger proportion of unmarried women age 15-24 want to postpone a birth for two or more years than do married women the same age, in almost every country. As with young married women, the preference to wait two or more years has become stronger over time among young unmarried women.
- Most married young women do not use any contraceptive method. Use of modern methods of contraception exceeds that of traditional methods. However, use of traditional methods is relatively high in Eastern Europe and Central Asia.
- A higher proportion of young unmarried women use contraception compared with their married counterparts. Nonetheless, the majority of women age 15-24 in all regions except Latin America and the Caribbean (44.6%) do not use any method of contraception: West and Central Africa (84.4%), East and Southern Africa (67.4%), Middle East and North Africa (55.5%), Eastern Europe and Central Asia (54.0%), and South and Southeast Asia (64.9%).
- Use of modern methods has increased over time among both married and unmarried young women.

Overall, unmet need for family planning has declined over time among young women age 15-24 in many countries—especially among young married women. However, levels of unmet need remain substantial in West and Central Africa. In general, sexually active unmarried women age 15-24 want to avoid a pregnancy to a greater degree than do married women. Unmet need is generally higher among unmarried women than married women, and higher among younger women (age 15-19) than older women (age 20-24).

# 1 Background

Unmet need for family planning has been an ongoing topic of fertility research since the 1960s when knowledge, attitude, and practice (KAP) surveys revealed a “KAP gap” in many countries. That is, given the stated fertility intentions of many women, nonuse of contraception is discrepant behavior. More than four decades after the concept’s emergence, unmet need has become a mainstay of demographic approaches to understanding fertility. It remains a critical measure for assessing women’s ability to achieve their reproductive intentions, estimating demand for family planning services, and monitoring the degree to which those services meet client needs.

In recent years, unmet need has received renewed attention as an advocacy and monitoring tool for family planning programs, becoming a key indicator (Indicator 5.6) for the Millennium Development Goals (MDG) (Inter-Agency and Expert Group on MDG Indicators (IAEG) 2008). It is an important measure for assessing progress toward the Family Planning 2020 goal to extend family planning services to an additional 120 million women and girls by 2020 (Carr et al. 2012; Horton and Peterson 2012). As such, new scrutiny has been focused on the way in which unmet need is measured, with the objective of assuring that it is calculated consistently over time and across settings.

The concept of unmet need for family planning is notable for bringing together in one measure both contraceptive behavior and fertility preferences, a feature that distinguishes it from other fertility-related measures such as the contraceptive prevalence rate (Casterline and Sinding 2000). At the heart of the concept is the prevention of unintended pregnancy among women who want to avoid pregnancy (Jain 1999; Yinger 1998). As such, the early, basic definition of unmet need can be described as the *proportion of married women who do not want any (more) births, but who are not using contraception* (Casterline and Sinding 2000; Freedman, Coombs, and Chang 1972).

Efforts to develop methods to quantify this group of women were made by both Nortman and Westoff, who expanded the original definition in two important ways (Nortman 1982; Westoff 1978, 1988; Westoff and Pebley 1981). First, it was expanded to include certain women who are temporarily infecund, recognizing that women who are currently pregnant, breastfeeding, or amenorrheic may soon experience unmet need (Nortman 1982). The second extension of the definition made the distinction between two types of unmet need: unmet need for spacing births and unmet need for limiting fertility (Westoff 1988). Since this early development, decomposing total unmet need into unmet need for spacing and unmet need for limiting has become standard practice.

Recent criticisms of the measurement of unmet need continue to raise concerns with *who* is included in the algorithms used to estimate unmet need. Mindful that the motivation behind the concept of unmet need is assessing the degree to which women can avoid unintended pregnancies, some have argued that the measure should include sexually active unmarried women or women using less efficacious methods of contraception (i.e. traditional methods), methods that are a poor fit for their reproductive goals or are otherwise inappropriate, or methods with which they are dissatisfied and which they may discontinue (Casterline and Sinding 2000; DeGraff and de Silva 1996; Dixon-Mueller and Germain 1992; Foreit and Mostajo 1993; Yinger 1998).

There has been a greater response to the first criticism than to criticisms regarding contraceptive methods. As the age of sexual debut has declined and sexual experience and fertility becomes increasingly separated from the institution of marriage in many countries (Kothari et al. 2012; Lloyd 2005), the exclusion of unmarried women from the unmet need algorithm has become increasingly problematic (Dixon-Mueller and Germain 1992; Yinger 1998). Currently, the field generally defines unmet need for family planning as the *proportion of fecund, sexually active women who want to limit or*

*delay childbearing (beyond two years), but who are not using contraception* (Becker 1999; Bongaarts and Bruce 1995; Casterline and Sinding 2000; Yinger 1998).

The Demographic and Health Surveys (DHS) Program has been collecting data with which to calculate unmet need for family planning since the first phase of survey implementation (1984-89). The DHS program has been collecting data on adolescents and youth for more than three decades (Kothari et al. 2012). An increasing number of surveys now interview both married and unmarried women alike, facilitating measurement of unmet need for both populations. However, the algorithm for estimating unmet need has evolved over time and been applied inconsistently. For example, there has been variation in 1) specification of the duration of postpartum amenorrhea, 2) application of a “contraceptive calendar,” and 3) use of data on contraceptive discontinuation (Bradley et al. 2012). Because international monitoring efforts (e.g., the MDGs and FP2020) require stable unmet need indicators, the DHS program recently undertook efforts to standardize and simplify the algorithm for unmet need. The results of this initiative reveal earlier estimates to have underestimated unmet need where contraceptive calendar data had been applied and smaller changes elsewhere (Bradley et al. 2012). Updated estimates for all women of reproductive age are reported in DHS Analytical Study No. 25 (Bradley et al. 2012).

Young women, particularly unmarried women, may disproportionately experience unmet need for family planning due to their unique fertility preferences associated with this stage of the life course. Alternately, they may experience higher levels of unmet need where they lack full knowledge of their options, access to services is lacking (particularly those designed for young people or for spacing needs generally), or where programs underestimate needs of youth. This study examines the current state of young women’s need for family planning and the extent to which unmet need in this population equals or exceeds unmet need in the general population of women of reproductive age. The study uses data from recent DHS surveys and applies the revised, standard definition of unmet need. This definition is fully comparable across settings and over time. This algorithm is applied both to married women and to unmarried women who have been sexually active within the 30 days preceding the survey.

## 1.1 Study Objectives

The study describes *current levels* of unmet need for family planning and demand for family planning among women age 15-24 and investigates *trends* in unmet need among young women since 1990. It makes *comparisons* based on age and examines the *socio-demographic factors* associated with unmet need, such as rural-urban residence, wealth, education, and parity. Finally, it explores current levels and trends in the *components* of unmet need, namely exposure to the risk of pregnancy through marriage or non-marital sexual activity, fertility preferences, and the use or non-use of contraception.

Specifically, this report addresses the following questions:

- In which regions/countries is unmet need and total demand for family planning higher/lower among young women?
- Has unmet need among young women declined over time? Which regions have had the sharpest decreases?
- How do women age 15-24 compare with women age 25-49 regarding unmet need? Are young women particularly disadvantaged?
- How does unmet need and total demand for family planning compare between young married women and young sexually active unmarried women?

- Which socio-demographic groups experience the highest levels of unmet need?
- What proportion of young women is married and what proportion is unmarried and sexually active? What are their fertility desires? What proportion of young women is using contraception? How many are using modern methods versus traditional methods? How have these patterns changed over time?

## 2 Data and Methods

This study uses Demographic and Health Survey (DHS) data from 142 surveys in 61 countries that conducted a DHS survey since the year 2000. Current survey data are supplemented by data from up to two prior surveys—supplying as many as three data points per country—to establish trends over time for 47 countries.

This study calculates total demand for family planning, unmet need for spacing and limiting, and proportion of demand satisfied for young women. Chapters 3 and 4 present current levels and trends in unmet need among married women by five-year age group (15-19 and 20-24); Chapter 5 presents this information for unmarried women and compares unmet need by marital status. Analysis of unmet need among unmarried women is necessarily limited to the 91 surveys in 41 countries that interviewed *all* women age 15-49; surveys that sampled only *ever-married* women are excluded. Chapter 6 combines DHS data on unmet need with population estimates from the U.S. Census Bureau to estimate the number of women age 15-24 with unmet need. Chapter 7 offers a more detailed examination of unmet need by two-year age group and compares young women 15-24 with women age 25 and older.

Chapter 8 presents the results of bivariate analyses of unmet need across the major socio-demographic variables: rural-urban residence, wealth quintile, educational attainment, and parity. Finally, Chapter 9 describes current levels and trends in the underlying components of unmet need for family planning. These components include two measures describing the population at risk of pregnancy: 1) proportion married or in union by exact ages 15 and 18, and 2) proportion unmarried and sexually active in the past 30 days; two measures describing fertility preferences: 1) desired ideal family size, and 2) fertility desires (wanting no more children, wanting a child after 2 years or more, wanting a child immediately); and current use of contraception (use of a modern method, a traditional method, or no method).

Throughout the study, we apply the revised algorithm for unmet need (Bradley et al. 2012). Use of the term “married women” refers to women in formal marriages or living in union. The revised algorithm for unmet need considers all women currently using any contraceptive method to have a met need for family planning, without distinction of method type. Where distinctions are made between use of modern methods and use of traditional methods, the following are classified as modern methods, in keeping with previous DHS work in this area (e.g. Westoff 2012): pill, IUD, injections, female or male condom, foam/jelly, diaphragm, implants, lactational amenorrhea method, and female or male sterilization. Traditional methods mainly comprise withdrawal and periodic abstinence.

The data are not pooled; rather analyses are conducted separately for each survey. All data are weighted within each survey to account for undersampling or oversampling of geographic districts and non-response; weighted sample sizes are reported throughout the study. Regional averages are calculated giving equal weight to each country, regardless of sample or population size.

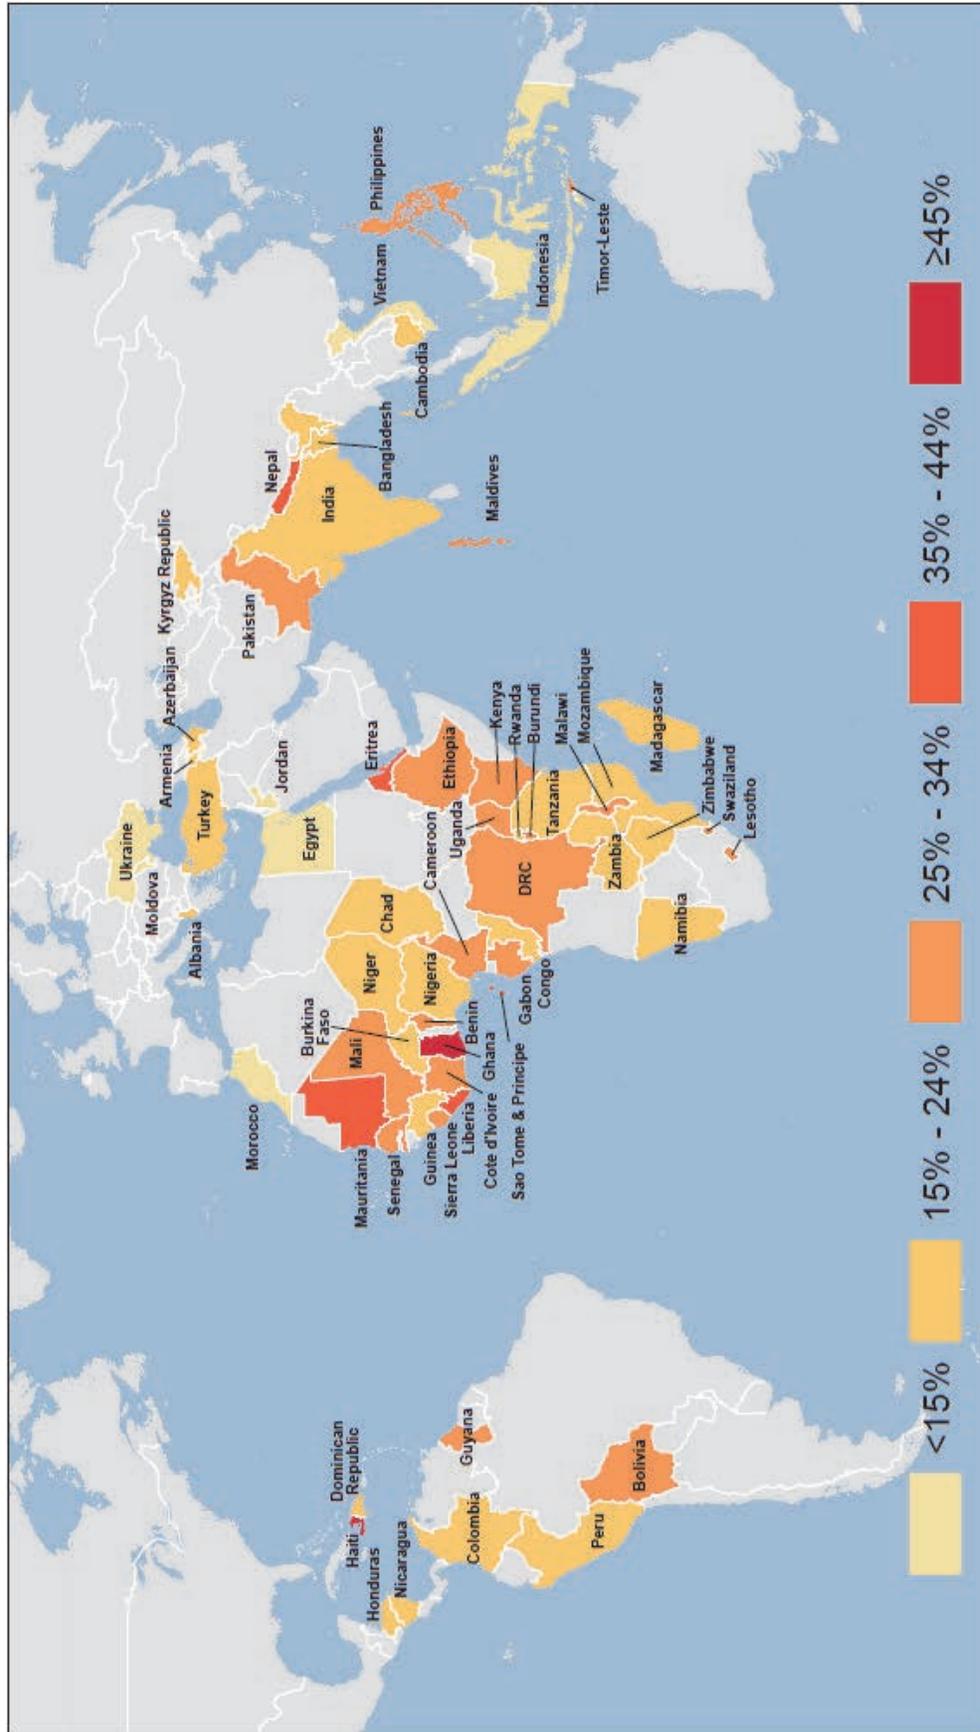

### **3 Current Levels of Unmet Need for Family Planning among Young Married Women**

#### **3.1 Geographic Distribution of Unmet Need for Family Planning among Young Married Women**

Map 1 displays the geographic distribution of the prevalence of unmet need for family planning among married women age 15-24. It indicates that, among young, married women, unmet need is *highest* in West African countries, namely in Eritrea, Ghana, Liberia, Mauritania, and São Tomé and Príncipe, and, in other regions, in Haiti, and Nepal. Unmet need among young married women is *lowest* in Indonesia and Vietnam in South and Southeast Asia and in many of the East European and Central Asian and Middle Eastern and North African countries surveyed.

Map 1. Unmet need for family planning among married women age 15-24

### 3.2 Unmet Need and Demand for Family Planning among Young Married Women

Table 1 presents the most recent DHS estimates of unmet need for family planning and current use of contraception among married women age 15-24. It also shows total demand for family planning, which is the sum of the percentage of women with unmet need plus the percentage currently using contraception (i.e., those with “met need”), and the proportion of demand satisfied, which is the percentage of women currently using contraception divided by total demand. The last column of Table 1 shows the rank order of each country according to level of unmet need among married women age 15-24.

On average among countries in this study<sup>1</sup>, unmet need among married women age 15-24 is highest in West and Central Africa, at nearly 30 percent; this region includes five of the top ten countries in terms of unmet need. West and Central Africa is followed by East and Southern Africa, Latin America and the Caribbean, and South and Southeast Asia, with one or two top ten countries each; in these regions, unmet need is experienced by nearly one-quarter of married women age 15-24. Unmet need is much lower in the Eastern Europe and Central Asia region and in the Middle East and North Africa region, where levels are generally below 20 percent. Among individual countries, unmet need among married women age 15-24 is highest in Ghana (45.7%) and Haiti (44.8%) and lowest in Indonesia (8.0%) and Egypt (8.8%).

<b>Regional average</b>		<b>24.5</b>	<b>55.4</b>	<b>79.9</b>	<b>69.3</b>	<b>18,838</b>	

Demand for family planning is substantially higher in Latin America and the Caribbean (79.9%) than in the other regions, indicating that high levels of use of contraception (55.4%) among young married women coexist with high levels of unmet need (24.5%). Demand for family planning is lowest, on average, in West and Central Africa (44.9%). Because unmet need is generally quite high, this region also has the lowest average proportion of demand satisfied (32.6%). This pattern contrasts with the Middle East and North Africa, which has the second lowest demand for family planning (55.3%) but the highest proportion of demand satisfied (80.5%). For the countries surveyed in this report, the overall proportion of demand that is satisfied averages 57.7 percent.

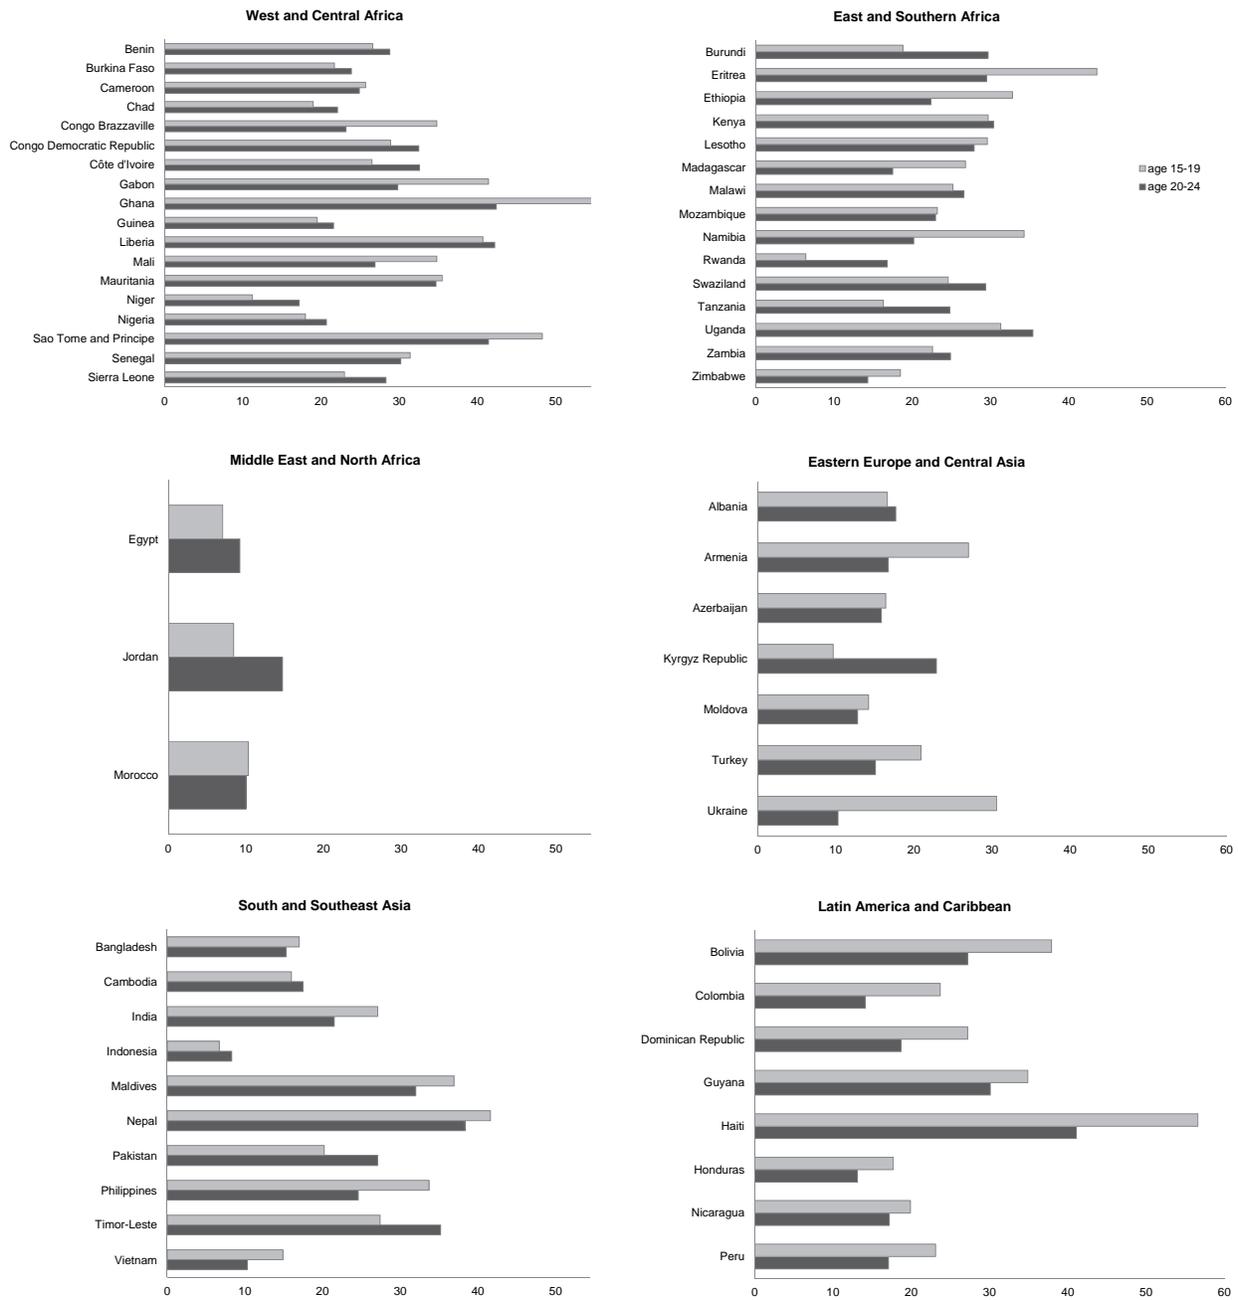

Figure 1 uses aggregate data for each region to compare unmet need, current use of contraception, and demand for family planning among young married women by five-year age group (15-19 and 20-24). Figure 2 compares levels of unmet need among married women age 15-19 and married women age 20-24 among individual countries in each region included in this study. Country-level details on unmet need, current use of contraception, total demand for family planning, and proportion of demand satisfied, by five-year age group (15-19 and 20-24) can be found in Appendix Table A1.

West and Central Africa has the highest level of unmet need in both age groups, followed by Latin America and Caribbean and East and Southern Africa in the 15-19 age group, then followed by East and Southern Africa and South and Southeast Asia in the 20-24 age group. In most regions, unmet need is higher among married women age 15-19 than those age 20-24. This difference is particularly acute in Latin America and the Caribbean where, on average, unmet need is nearly eight percentage points higher among married women age 15-19. The Middle East and North Africa, where unmet need is relatively low, is the only region where the opposite pattern is observed. In Egypt and Jordan, unmet need is higher among married women age 20-24 than among those age 15-19; in Morocco, there is little difference between the two age groups. Demand for family planning and the proportion of demand satisfied are higher among married women age 20-24 than among those age 15-19 in every region.

**Figure 1. Regional comparison of unmet need for family planning, current use of contraception, and percentage of demand satisfied between currently married women age 15-19 and currently married women age 20-24, most recent DHS surveys, 2000-2012**

**Figure 2. Comparison of total unmet need for family planning between currently married women age 15-19 and age 20-24, most recent DHS surveys, 2000-2012**

### **3.2.1 West and Central Africa**

While West and Central Africa has the highest average level of unmet need (29.3%), the regional average masks substantial variation (Table 1). Unmet need ranges from 14.7 percent among married women age 15-24 in Niger to 45.7 percent in Ghana. In these same countries, unmet need ranges from 11.2 to 61.7 percent among women age 15-19 compared with 17.2 to 42.4 percent among women age 20-24 (Figure 2). Along with Ghana (45.7%), São Tomé and Príncipe (43.3%), Liberia (41.8%), Mauritania (35%), and Gabon (32.7%) are all included in the ten study countries with the highest levels of unmet need among young married women. Meanwhile, Guinea (20.8%), Niger (14.7%), and Nigeria (19.8%) stand out as having relatively low levels of unmet need in the region. Comparing the two age groups (married women age 15-19 and married women age 20-24) in Figure 2, neither age group has consistently greater unmet need than the other; however, where differences are greatest, unmet need is higher among married women age 15-19.

Demand for family planning is lowest in Niger (23.9%) and Nigeria (27.5%) and highest in São Tomé and Príncipe (77.5%), Congo (Brazzaville, 69.6%), and Ghana (66.6%) (Table 1). The proportion of demand satisfied is highest in Congo (Brazzaville) at 62.1 percent, the only country in the region to exceed 50 percent. The proportion of demand satisfied is particularly low in Sierra Leone (13.6%), Liberia (13.6%), and Mauritania (15.3%).

### **3.2.2 East and Southern Africa**

Several points are notable regarding patterns of unmet need among married women age 15-24 in East and Southern Africa (Table 1). First, while unmet need is relatively high overall (25.5%), few countries in this region have levels of unmet need that exceed 30 percent compared with West and Central Africa. These are Eritrea (34.8%), Kenya (30.2%), and Uganda (34.3%). Second, there is less variation across countries than in West and Central Africa. Unmet need among married women age 15-24 is lowest in Rwanda (16%) and Zimbabwe (15.5%); the remaining ten countries in the region have levels of unmet need between 20 and 29 percent.

While, on average, unmet need is greater among married women age 15-19 compared with those age 20-24, there is no consistent pattern as to which age group is more disadvantaged with regard to unmet need at a national level (Figure 2). Unmet need is substantially higher among those age 15-19 in Eritrea, Ethiopia, Madagascar, and Namibia, higher among those age 20-24 in Burundi, Rwanda, and Tanzania, and nearly equal in Kenya, Lesotho, Malawi, Mozambique, and Zambia.

On average, total demand for family planning in East and Southern Africa exceeds that in West and Central Africa and the Middle East and North Africa, and is similar to that in South and Southeast Asia (Table 1). It ranges from a low of 32.6 percent in Mozambique and 39.3 percent in Eritrea to a high of 74.3 percent in Swaziland and 74.7 percent in Namibia. The regional average is 58.1 percent. In Eritrea and Mozambique, unmet need combines with low levels of use of contraception (4.5% and 9.5%, respectively) to produce a low proportion of demand satisfied (11.5% and 29.1%, respectively). The country with the highest proportion of demand satisfied among married women age 15-24 is Zimbabwe (77.6%), which also has the lowest level of unmet need (15.5%) and the highest level of use of contraception (53.7%) in the region.

### **3.2.3 Middle East and North Africa**

In the Middle East and North Africa, low level of unmet need (10.8%) among married women age 15-24 combine with low demand for family planning (55.3%) such that a high proportion of that demand is satisfied (80.3%) by use of contraception (44.5%) (Table 1). Within this region, unmet need is

lowest in Egypt (8.8%) and highest in Jordan (13.5%). While unmet need is generally higher among married women age 20-24 compared with those age 15-19 year olds (a different pattern than found in other regions), this difference is particularly pronounced in Jordan where unmet need is 6.3 percentage points higher among married women age 20-24 (14.7%) than among those age 15-19 (8.4%) (Figure 2).

### **3.2.4 Eastern Europe and Central Asia**

After the Middle East and North Africa, the Eastern Europe and Central Asia region has the second lowest level of unmet need (16.2%) among married women age 15-24 (Table 1). Unmet need ranges from 12.0 percent in Ukraine to 20.9 percent in the Kyrgyz Republic. As in most other regions, unmet need is higher among married women age 15-19 in some countries and higher among married women age 20-24 in other countries (Figure 2). Differences are particularly large in several countries. Unmet need is more than 10 percentage points higher among married women age 15-19 (27.0%) in Armenia than among those age 20-24 (16.7%) and approximately three times higher in Ukraine (30.6% and 10.3%, respectively). In contrast, unmet need is twice as high among married women age 20-24 as among those age 15-19 in the Kyrgyz Republic.

Use of contraception is relatively high among married women age 15-24 in Eastern Europe and Central Asia, compared with other regions (Table 1). Total demand and the proportion of demand satisfied, therefore, is also generally high. For example, in Turkey, 58.5 percent of married women age 15-24 are currently using contraception. Combined with the 16.2 percent of women who have an unmet need for family planning, the total demand for family planning is 74.7 percent; however, more than three-quarters (78.3%) of that demand is satisfied.

### **3.2.5 South and Southeast Asia**

Unmet need among married women age 15-29 in South and Southeast Asia ranges from a high of 39.3 percent in Nepal to a low of 8.0 percent in Indonesia (Table 1). The average of the countries surveyed in the region is 23.2 percent. Current use of contraception is high in Indonesia (58.2%), Bangladesh (54.0%), and Vietnam (53.8%) and low in Pakistan (13.0%) and Timor-Leste (14.3%). Total demand for family planning is lowest in Pakistan (38.2%), where just over one-third (34.0%) of that demand is satisfied. Total demand is highest in Bangladesh (69.9%), with more than three-quarters (77.3%) of that demand satisfied. On average, the demand profile in South and Southeast Asia resembles that in East and Southern Africa, with total demand for family planning estimated at 58.4 percent and more than half (60.2%) of that demand satisfied. While demand for family planning is consistently higher among married women age 20-24, compared with those age 15-19, there is no clear, region-wide pattern regarding age and unmet need (Figure 2).

### **3.2.6 Latin America and the Caribbean**

In Latin America and the Caribbean, levels of unmet need among married women age 15-24 are similar to those in South and Southeast Asia and East and Southern Africa, averaging 24.5 percent in surveyed countries (Table 1). There is considerable variation within the region, however. Haiti has the second highest level of unmet need (44.8%) among all the countries surveyed in the study. Unmet need is also relatively high in Guyana (31.5%) and Bolivia (30.1%), at about 30 percent. Honduras has the lowest level of unmet need in the region (14.7%). Unmet need in the remaining Latin America and Caribbean countries ranges from 16.8 percent in Colombia to 21.5 percent in the Dominican Republic.

The Latin America and the Caribbean region has the highest average levels of use of contraception (55.4%) and the highest total demand for family planning (79.9%) of all the regions in the

study. However, with just 69.3 percent of demand satisfied, demand still outpaces use of contraception, which puts Latin America and the Caribbean in the middle of all the regions for which DHS data are available.

There is little variation in levels of demand for family planning, which range from 67.5 percent in Guyana to 88.7 percent in Peru. Variations in levels of unmet need and use of contraception do combine, however, to produce substantial variation in the proportion of demand satisfied, from a low of 42.7 percent in Haiti to a high of 81.4 percent in Honduras. Use of contraception is generally high in the region, with the exception of Guyana and Haiti, where a little more than one third of married women age 15-24 currently use some method of contraception, levels that are low for this region.

### **3.3 Unmet Need for Spacing and for Limiting among Young Married Women**

Unmet need for spacing comprises women who want to delay a birth two or more years, whereas unmet need for limiting comprises women who want to avoid a subsequent birth altogether. Table 2 presents the most recent DHS estimates of unmet need for spacing and unmet need for limiting among married women age 15-24. A disaggregation of these data by five-year age group is provided in Appendix Table A2.

The overwhelming majority of unmet need for family planning among married women age 15-24 in all surveyed countries is unmet need for spacing. Unmet need for limiting contributes little to the overall level of unmet need. This finding is not surprising given that women in this age range are more likely to be at an early stage in their reproductive careers. Perhaps more surprising, then, is the existence of noticeably sizable levels of unmet need for limiting—greater than 10 percent in at least one age group—in one or more countries in nearly every region. These countries are Ghana and São Tomé and Príncipe in West and Central Africa, Swaziland in East and Southern Africa, Nepal, in South and Southeast Asia, and Bolivia and Guyana in Latin America and the Caribbean. Unmet need for limiting is rare in the Middle East and North Africa and in Eastern Europe and Central Asia, although levels are not negligible in Azerbaijan (6.3%) and Turkey (4.2%).

Unmet need for limiting is generally interpreted as unmet need arising at a stage of the life cycle when women have already met (or exceeded) their desired fertility. Thus, it would be expected to occur among young women in those settings where childbearing begins at an early age, particularly if desired family size is small and/or births tend to be closely spaced. It is also possible that unmet need for limiting among young women represents a growing desire to remain childless throughout one's life, in which case unmet need for limiting would be reported among nulliparous women. Alternately, unmet need for limiting may arise out of the way in which women, particularly young women, report their fertility desires. That is, women report their current fertility desires at the time of the survey, and these desires may change over time. It may be entirely consistent for a woman to report that she does not want any (more) children at one point in time and, at a future point in time, to report that she does want another child. To the extent that this phenomenon occurs disproportionately among young women—because these women have a longer period of time in which to change their fertility desires—there may be some amount of unmet need for limiting that is overestimated and is perhaps better characterized as unmet need for spacing. None of these potential explanations are explored empirically in this study.

**Table 2. Unmet need for spacing and for limiting among currently married women age 15-24, most recent DHS surveys, 2000-2012**

Each of the countries listed above as having unmet need for limiting greater than 10 percent in either or both age groups also has a relatively high level of total unmet need, ranking among the top third of surveyed countries. This pattern is by no means universal, as counterexamples elsewhere demonstrate: Azerbaijan, Malawi, Namibia, Nicaragua, and the Philippines all have non-negligible levels of unmet need for limiting in both age groups (ranging from 5% to 10%), but Azerbaijan and Nicaragua rank among the lowest third of countries for total unmet need, while the others rank in the middle third for total unmet need. This finding suggests that total unmet need and unmet need for limiting are not consistently correlated. Neither does there seem to be a pattern with regards to unmet need for limiting and age (see Appendix Table A2). Among countries with non-negligible levels of unmet need for limiting (5% to 10%), unmet need for limiting is higher among married women age 20-24 just as frequently as it is lower in this age group.

## 4 Trends in Unmet Need for Family Planning among Young Married Women

Of the 61 countries included in this report, 47 have multiple surveys that can be used to examine trends over time in unmet need for family planning among married women. Multiple surveys are available for 13 countries in each of the two African regions, three countries each in the Middle East and North Africa and Eastern Europe and Central Asia, eight countries in South and Southeast Asia, and seven countries in Latin America and the Caribbean.

### 4.1 Trends in Unmet Need and Demand for Family Planning among Young Married Women

Table 3 presents trends in the levels of unmet need, current use of contraception, total demand for family planning, and the proportion of demand satisfied for married women age 15-24 in the 47 countries in which multiple surveys have been conducted. Appendix Table A3 provides these trends data by five-year age group (15-19 and 20-24). No statistical tests were conducted to determine if observed changes over time are significant.

Generally, the situation trends toward a decline in levels of unmet need among married women age 15-24. This trend is frequently accompanied by increases in current use of contraception that have kept pace with or exceeded increases in total demand for family planning, with the result that the proportion of demand satisfied has also increased over successive surveys. These trends vary in degree and pace of change within and across regions, and have not everywhere been universal in their direction toward reduced unmet need. Of concern are the 10 countries in which women age 15-24 have experienced an *increase in unmet need* over time: Benin, Cameroun, Chad, Congo (Brazzaville), Gabon, and Mali (West and Central Africa), Eritrea and Zimbabwe (East and Southern Africa), Kyrgyz Republic (Eastern Europe and Central Asia), and Nepal (South and Southeast Asia).

Peru	2000	22.0	62.1	84.1	73.8	2,551

#### **4.1.1 West and Central Africa**

Four countries in West and Central Africa—Burkina Faso, Guinea, Niger, and Senegal—show decreasing unmet need among young married women while six countries—Benin, Cameroun, Chad, Congo (Brazzaville), Gabon, and Mali—show increasing unmet need. Levels of unmet need have fluctuated in the remaining three countries, without a clear trend. This stands in contrast to other regions in which a majority of countries show a trend of declining unmet need among married women age 15-24.

#### **4.1.2 East and Southern Africa**

The majority of countries in East and Southern Africa show declines in unmet need over time among married women age 15-24. The decline is particularly notable in Ethiopia where unmet need fell 12.6 percentage points between 2000 and 2011. This trend is accompanied by a dramatic increase in current use of contraception, from 6.3 percent among married women age 15-24 in 2000 to 31.5 percent in 2011—and a nearly four-fold increase in the proportion of demand satisfied. Substantial changes are also evident in Madagascar, where unmet need declined more than six percentage points between 1997 and 2008-09; this decline was accompanied by an almost tripling of use of contraception (from 12.3% to 32.1%) and a near doubling of the proportion of demand satisfied (from 31.1% to 60.2%).

In contrast to the dominant trend in the region, two countries, Eritrea and Zimbabwe, experienced increases in unmet need among married women age 15-24. Three countries show fluctuations in the level of unmet need with no clear trend.

#### **4.1.3 Middle East and North Africa**

Egypt, Jordan, and Morocco all experienced declining unmet need among married women age 15-24. Use of contraception and, therefore, demand for family planning have fluctuated over time. The general trend is toward greater use of contraception and the proportion of demand satisfied also trends upward.

#### **4.1.4 Eastern Europe and Central Asia**

Armenia and Turkey show steady progress toward lower levels of unmet need among married women age 15-24, accompanied by increases in use of contraception (in Turkey), demand for family planning, and the proportion of demand satisfied. On the other hand, the Kyrgyz Republic exhibits a deteriorating situation with regards to unmet need. Unmet need among married women age 15-24 increased 8.6 percentage points and current use of contraception fell sharply from 45.5 percent in 1997 to 19.3 percent in 2012. While total demand for family planning declined so did the proportion of demand satisfied, from more than three-quarters to less than half of married women age 15-24 with a need for family planning.

#### **4.1.5 South and Southeast Asia**

Seven of the eight countries in South and Southeast Asia with multiple surveys exhibit the general pattern of declining unmet need and increasing use of contraception, demand for family planning, and proportion of demand satisfied among married women age 15-24. These trends are particularly pronounced in Cambodia and Pakistan. In Indonesia, unmet need is lower (8.0%) in 2012—and proportion of demand satisfied is higher—than in either of the two preceding surveys (9.0% in 2002-03 and 9.8% in 2007); however, the decline was not steady, but occurred after an increase in 2007. Also, levels of use of contraception in Indonesia fluctuated across successive surveys. The trend in unmet need

in Nepal is the opposite of the general pattern, with unmet need increasing from 33.8 percent in 2001 to 39.3 percent a decade later. Use of contraception increased during this period but it is overshadowed by a 12 percentage point increase in the demand for family planning.

#### 4.1.6 Latin America and Caribbean

The countries surveyed in Latin America and the Caribbean show that in general unmet need has declined among married women age 15-24 and the proportion of demand for family planning satisfied has increased over time. While unmet need in Haiti is lower in 2012 (44.8%) than it was in 2000 (46.4%), there appears to have been a slight increase since the intervening survey in 2005-06 (43.9%). At the same time, current use of contraception, demand for family planning, and the proportion of demand satisfied all increased in Haiti. On the other hand, Bolivia shows a steady decline in unmet need between 1998 (33.8%) and 2008 (30.1%) but use of contraception has fluctuated. It appears that in Bolivia the greatest changes in unmet need and use of contraception occurred between the 1998 and 2003 surveys, with more modest changes occurring between the 2003 and 2008 surveys.

## 4.2 Trends in Unmet Need for Spacing and for Limiting among Young Married Women

Table 4 presents levels of unmet need for spacing and limiting among married women age 15-24 in countries where multiple surveys have been conducted. Appendix Table A4 displays trends in unmet need for spacing and limiting in this population by five-year age group (15-19 and 20-24). The trends for *spacing* mirror the trends for *total unmet need* because spacing accounts for almost all unmet need. Among successive surveys, unmet need for spacing among married women age 15-24 is consistently higher—usually substantially so—than unmet need for limiting. This is generally the case for both age groups (15-19 and 20-24) as well (Appendix Table A4). Trends in unmet need for limiting show no clear pattern within or across regions, and because unmet need for limiting is low overall, differences in successive surveys are generally small. As with other trend data presented in this report, no statistical tests were conducted to determine if changes over time are statistically significant.

**Table 4. Trends in unmet need for spacing and for limiting among currently married women age 15-24**

#### **4.2.1 West and Central Africa**

Table 4 indicates that, in Ghana, unmet need for limiting has been increasing. The increase is most pronounced in the younger age group, rising from 3.3 percent in 1998 to 6.2 percent in 2003 and to 12.7 percent in 2008, approximately doubling between each survey (see Appendix Table A4). In Cameroon, unmet need for limiting among married women age 15-24 declined from 3.5 percent in 1998 to less than two percent in subsequent surveys. Mali, which showed low levels of unmet need for limiting in 1995-96 (1.2%) and in the most recent survey in 2006 (1.4%), saw a sharp, temporary increase in unmet need for limiting in the intervening survey in 2001 (4.8%).

#### **4.2.2 East and Southern Africa**

In countries throughout the region there has generally been a decrease in unmet need for limiting among young married women. These declines have been particularly large in Lesotho, especially among those age 15-19 (from 16.4% to 3.3%), and in Madagascar, especially among those age 20-24 (from 7.9% to 1.7%) (see Appendix Table A4). For several countries, e.g., Ethiopia, Namibia, Rwanda, and Zimbabwe, the decline in unmet need for limiting follows a spike in an intervening survey. Kenya and Zambia contradict the prevailing trends in East and Southern Africa; in these two countries, unmet need for limiting has increased over time.

#### **4.2.3 Eastern Europe and Central Asia**

In all the countries surveyed in Eastern Europe and Central Asia unmet need for limiting has declined over time. The trend is largely driven by changes in need status among married women age 20-24, because there are fewer married women age 15-19 in this region (see Appendix Table A4). While levels of unmet need for limiting are now quite modest in Armenia (1.7%) and Turkey (4.2%), according to the most recent surveys, levels were markedly higher 10 years prior (Table 4).

#### **4.2.4 South and Southeast Asia**

Trends in unmet need for limiting among married women age 15-24 in South and Southeast Asia are mixed (Table 4). Declines are observed in Cambodia, the Philippines, and Vietnam. In Cambodia, for example, unmet need for limiting in 2010 (3.8%) fell to about half the level it had been a decade earlier (7.0%). However, unmet need for limiting increased in India and Nepal, countries that have some of the highest levels of unmet need for limiting among young married women. In India, increases in unmet need for limiting are offset by substantial decreases in unmet need for spacing, resulting in decreases in total unmet need. In Nepal increases in unmet need for limiting have been accompanied by increases in unmet need for spacing, resulting in increases in total unmet need. There has been little change in unmet need for limiting in Bangladesh and Pakistan. In these two countries declines in total unmet need are accounted for by declines in unmet need for spacing.

#### **4.2.5 Latin America and Caribbean**

Unmet need for limiting among married women age 15-24 has been, and remains, higher in Latin America and the Caribbean than in the other regions. The countries surveyed in Latin America and the Caribbean have largely experienced declines in unmet need for limiting that mirror declines in total unmet need; however, levels in many countries are still comparatively high. Bolivia has the highest level of unmet need for limiting in the region, 12.4 percent in 2008, but it has experienced a steady decline from 16.2 percent in 1998. In contrast, the level of unmet need for limiting in Colombia (4.3% in 2010) has not changed since 2000, although unmet need for spacing and thus total unmet need have both fallen during

this period. In Haiti, unmet need for limiting (8.3% in 2012) has returned to near 2000 levels (8.4%) despite a three percentage point decline in 2005-06 (5.4%); unmet need for spacing fell slightly during this period.

Because unmet need for limiting accounts for such a small proportion of overall unmet need for family planning, this study does not draw any further distinctions between unmet for spacing and unmet need for limiting.

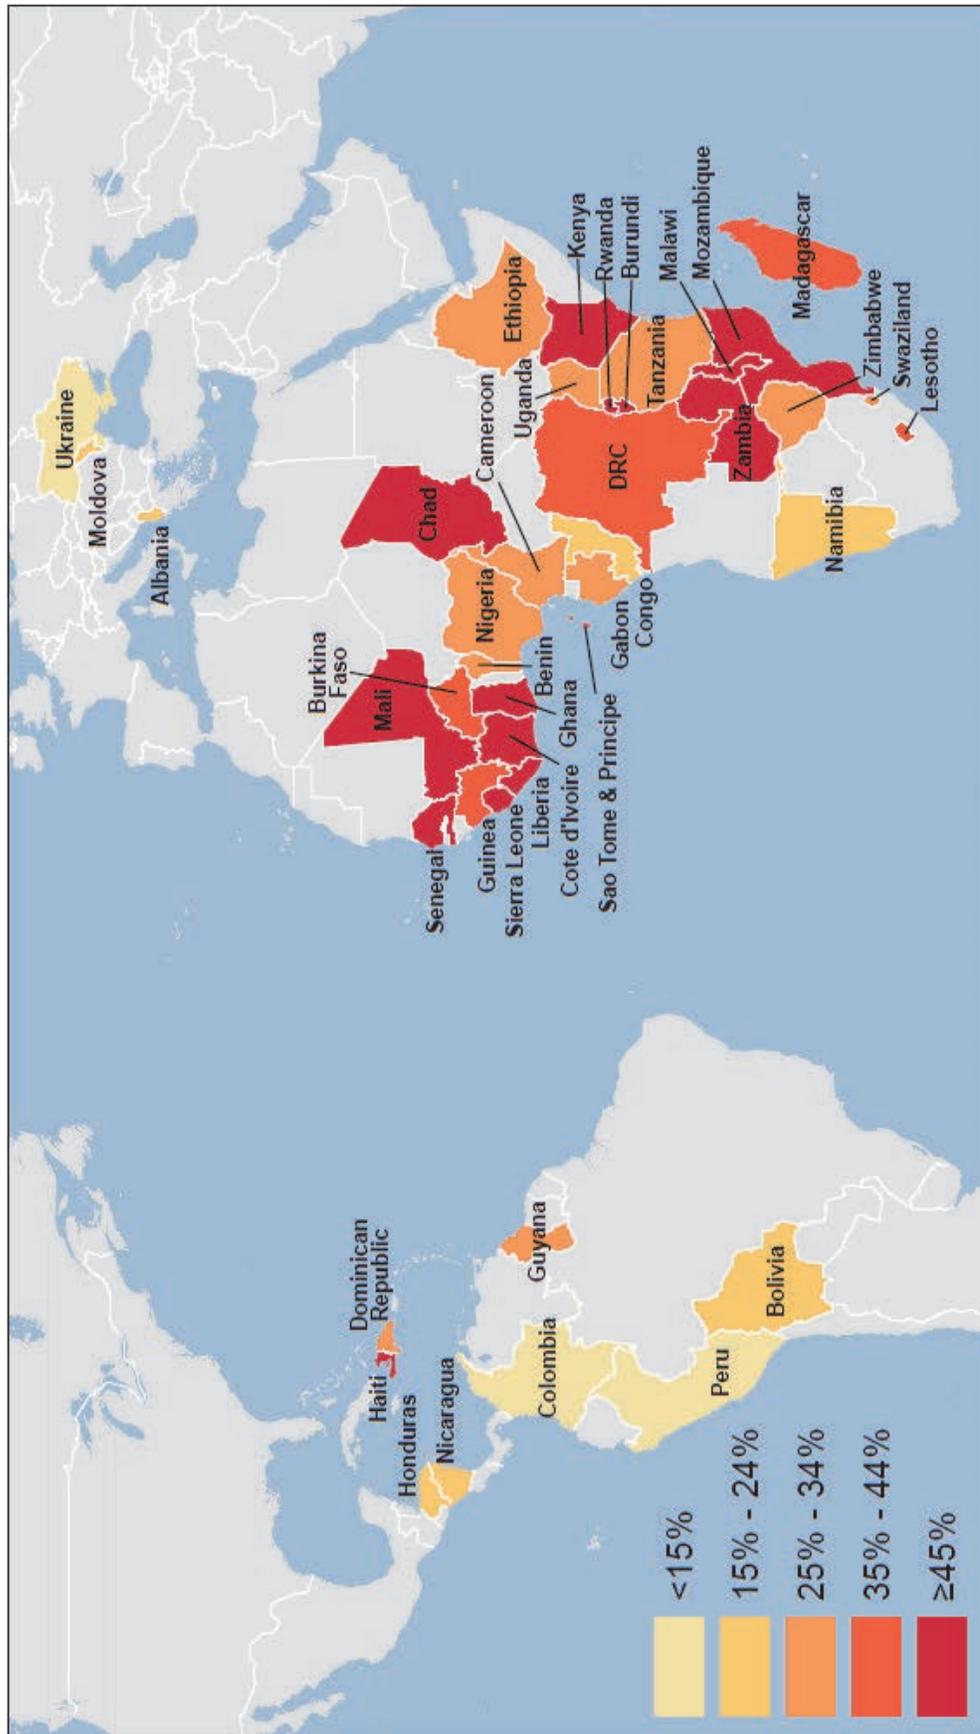

## **5 Unmet Need for Family Planning among Young Unmarried Women**

### **5.1 Geographic Distribution of Unmet Need for Family Planning among Young Unmarried Women**

Map 2 displays the geographic distribution of the prevalence of unmet need for family planning among sexually active, unmarried women age 15-24. Forty-one of the 61 countries included in this study have the necessary survey data by which to estimate unmet need in this population. No countries in the Middle East and North Africa region, in the South and Southeast Asia region, and few countries in the Eastern Europe and Central Asia region collected these data. The map uses the same scale as Map 1, which illustrates the prevalence of unmet need among young *married* women. Map 2 indicates that, among sexually active, unmarried women age 15-24, unmet need is highest in the two African regions and in Haiti. Unmet need is lowest in Colombia, Peru, and the Ukraine.

Map 2. Unmet need for family planning among unmarried, sexually active women age 15-24

## 5.2 Unmet Need and Demand for Family Planning among Young Unmarried Women

Table 5 presents the most recent DHS estimates of unmet need for family planning, current use of contraception, total demand for family planning, and the proportion of demand satisfied, among sexually active, unmarried women age 15-24. The last column of the table shows the rank order of each country according to level of unmet need. Recall that the algorithm for calculating unmet need among unmarried women defines “sexually active” based on respondents’ reports of having had sexual intercourse within the 30 days prior to the survey. Any underreporting of sexual activity by unmarried women due to social desirability bias is likely to bias downward estimates of unmet need in this population (Lavrakas 2008). Thus, this study may underestimate the true magnitude of unmet need among young unmarried women.

Unmet need among sexually active, unmarried women age 15-24 ranges from a low of 7.3 percent in Ukraine to a high of 69.5 percent in Senegal. Countries in West and Central Africa and East and Southern Africa have, on average, the highest levels of unmet need among unmarried women, at about 40 percent. Unmet need is lowest, on average, in the three countries in Eastern Europe and Central Asia, where it averages 15.4 percent. Correspondingly, use of contraception is highest in Eastern Europe and Central Asia (80%) and lowest in the two African regions (46.6% and 46.3%, respectively).

Figure 3 displays aggregate data for each region with which to compare sexually active, unmarried women age 15-19 and age 20-24 on unmet need, current use of contraception, and total demand for family planning. Appendix Table A5 provides these data for individual countries in this study. Looking at the two age groups that comprise the population of sexually active, unmarried women in this study, there is little difference in total demand for family planning: similar proportions of those age 15-19 and those age 20-24 want to avoid pregnancy. However, differences between age groups in unmet need for family planning and use of contraception are substantial. In all regions except Eastern Europe and Central Asia, unmet need is at least ten percentage points *higher* and use of contraception is about ten percentage points *lower* among sexually active, unmarried women age 15-19 compared with those age 20-24. In Eastern Europe and Central Asia there is almost no difference between the two age groups.

**Figure 3. Regional comparison of unmet need for family planning, current use of contraception, and percentage of demand satisfied between sexually active, unmarried women age 15-19 and currently married women age 20-24, most recent DHS surveys, 2000-2012**

### 5.2.1 West and Central Africa

Table 5 indicates that, on average, West and Central Africa has the highest levels of unmet need among sexually active, unmarried women age 15-24 (41.7%). Seven of the ten countries with the highest levels of unmet need among those surveyed are in this region. They are Senegal (69.5%), Liberia (58.1%), Chad (56.8%), Côte d’Ivoire (50.6%), Mali (50.1%), Ghana (48.7%), and Sierra Leone (47.4%). However, unmet need is not universally high throughout the region. Cameroon (25.5%) and Congo (Brazzaville) (17.1%), for instance, rank in the lowest third among the countries surveyed.

Use of contraception among sexually active, unmarried women age 15-24 varies greatly in the region, from a low of 9.8 percent in Chad to a high of 75.7 percent in Congo (Brazzaville). Because demand for family planning is consistently high in West and Central Africa (averaging 88.4%)—Chad (66.6%) is an outlier—it is primarily use of contraception that dictates the proportion of demand for family planning that is satisfied. The proportion of demand satisfied ranges from 26.1 percent in Senegal where use of contraception is lowest to 81.6 percent in Congo (Brazzaville) where use of contraception is highest.

### 5.2.2 East and Southern Africa

East and Southern Africa closely follows West and Central Africa with unmet need averaging 39.8 percent among sexually active, unmarried women age 15-24 (Table 5). Two of the ten countries with the highest levels of unmet need—Burundi (62.2%) and Rwanda (54.4%)—are in this region. As with

West and Central Africa, two countries (Ethiopia and Namibia) rank in the lowest third among those surveyed. Unmet need ranges greatly from a low of 16.1 percent of sexually active, unmarried women age 15-24 in Namibia to 62.2 percent in Burundi. Current use of contraception has a similarly wide range, from 77.2 percent in Namibia to 16.7 percent in Burundi. These disparate combinations of unmet need and use of contraception yield total demand for family planning that falls in a more narrow range from 78.6 percent in Mozambique to 94.0 percent in Swaziland. At the same time, the proportion of demand satisfied ranges from a low of 21.2 percent in Burundi to 82.7 percent in Namibia. Looking at the two age groups of sexually active, unmarried women, unmet need in the countries in East and Southern Africa is nearly always higher and use of contraception lower among those age 15-19 compared with those age 20-24 (Appendix Table A5).

### **5.2.3 *Eastern Europe and Central Asia***

Only three countries in Eastern Europe and Central Asia—Albania, Moldova, and Ukraine—collected the relevant data for estimating unmet need among sexually active, unmarried women age 15-24. This region has the lowest level of unmet need (15.4%), the highest level of use of contraception (80.0%), and the highest total demand for family planning (95.4%) among the countries providing this data (Table 5). Albania and Moldova are similar with regard to the proportion of sexually active, unmarried women age 15-24 who are currently using contraception (77.3% and 72.3%, respectively), although unmet need is slightly higher in Moldova (23.3%) than in Albania (15.6%). Use of contraception in Ukraine (90.4%) is the highest of all the countries in the study; Ukraine also has the lowest level of unmet need (7.3%) among sexually active, unmarried women age 15-24.

### **5.2.4 *Latin America and Caribbean***

Unmet need among sexually active, unmarried women age 15-24 in Latin America and the Caribbean is not as low as it is in Eastern Europe and Central Asia, but with an average of 24.9 percent among the countries supplying data, the region fares substantially better than the two African regions (Table 5). Relatively high levels of current use of contraception (67.6 % on average) contribute to the high proportion of demand for family planning satisfied (73.1 percent).

Haiti stands out from its regional neighbors with a relatively high level of unmet need among sexually active, unmarried women age 15-24 (58.8%), the third highest among all the countries surveyed. It also has the lowest level of use of contraception in this population in the Latin America and Caribbean region (35.1%) and the lowest proportion of demand satisfied (37.4%). Peru stands out from its neighbors for the opposite reason. Unmet need in Peru (8.9%) is the lowest in the region and second lowest (after Ukraine) among all the countries surveyed. Although Peru does not have the highest total demand for family planning in the region (96.8%), it does have the highest level of current use of contraception among sexually active, unmarried young women (87.9%) and the highest proportion of demand satisfied (90.8%) in the region.

Excluding Haiti and Peru, unmet need among sexually active, unmarried women age 15-24 in the remaining countries in the region ranges from 14.4 percent in Colombia to 29.3 percent in the Dominican Republic. Current use of contraception among this population in the Latin America and Caribbean region ranges from 35.1 percent in Haiti or, excluding this outlier, from 54.8 percent in the Dominican Republic to 87.9 percent in Peru. There is less variation in total demand for family planning, which exceeds 90 percent in most countries. In only two of the eight countries in this region, the Dominican Republic and Nicaragua, is total demand somewhat lower, at about 85 percent. The proportion of demand satisfied ranges from 37.4 percent in Haiti or, again excluding this outlier, from 65.2 percent in the Dominican Republic to 90.8 percent in Peru.

### 5.3 Trends in Unmet Need and Demand for Family Planning among Young Unmarried Women

Table 6 presents trends in unmet need, current use of contraception, total demand for family planning, and proportion of demand satisfied for countries in which multiple surveys collected data on sexually active, unmarried women age 15-24. No country in Eastern Europe conducted multiple surveys of this population, so data are shown only for West and Central Africa, East and Southern Africa, and Latin America and the Caribbean. These trends are disaggregated by five-year age group (15-19 and 20-24) in Appendix Table A6. As noted elsewhere in this study, no statistical tests were conducted to determine if observed changes over time are statistically significant.

**Table 6. Trends in unmet need for family planning, current use of contraception, and demand for family planning among sexually active, unmarried women age 15-24**

### 5.3.1 West and Central Africa

In the majority of countries in West and Central Africa, unmet need has increased among sexually active, unmarried women age 15-24. This is the case for eight of the 11 countries with trend data: Cameroon, Chad, Côte d'Ivoire, Congo, Gabon, Ghana, Guinea, and Mali. In some countries such as Burkina Faso and Guinea, there have been increases in unmet need among young unmarried women at the same time there have been decreases among their married counterparts.

Chad and the Côte d'Ivoire illustrate two contrasting patterns of increasing unmet need. Use of contraception has been relatively static in Chad; the increase over time in unmet need accounts entirely for the concurrent increase in demand for family planning. In Côte d'Ivoire, demand for family planning has remained high, but a decline in use of contraception of about 20 percentage points resulted in a sharp increase in unmet need.

In the remaining three countries, Benin, Burkina Faso, and Nigeria, unmet need has declined over time among young unmarried women, although some countries with three surveys show fluctuations in the downward trend. Benin and Nigeria had large increases in unmet need in the intervening surveys (2001 in Benin and 2003 in Nigeria) before settling at levels barely lower than those of surveys in the late 1990s.

### 5.3.2 East and Southern Africa

Unmet need among sexually active, unmarried women age 15-24 has generally fallen in East and Southern Africa. Six countries have seen declines: Ethiopia, Kenya, Lesotho, Malawi, Tanzania, and Zambia; however, these declines have not always been steady. Fluctuations in levels of unmet need in

Kenya and Zambia, for example, suggest a need for longer term data to establish the overall direction of trends.

Levels of unmet need have also fluctuated in Mozambique, Namibia, and Zimbabwe, without clear indication of increasing or decreasing trends. In Namibia, unmet need, which was strikingly low among young unmarried women in 1992 (8.4%)—as was overall demand for family planning (43.6%)—more than tripled by 2000 (29.4%); this was followed by a decline in 2006-07 (16.1%), although this level of unmet need is still nearly double that of 1992. In Mozambique, unmet need was initially relatively high at 52.4 percent in 1997 before falling to 28.1 percent in 2003 and then rising to 47.2 percent in 2011. Modest increases in demand for family planning mean that movement in one direction in the level of unmet need is accompanied by movement in the level of use of contraception in the opposite direction—i.e., increases in unmet need are accompanied by declines in use of contraception, and vice versa.

In Uganda and Madagascar, unmet need has increased although the magnitude of these changes is very small. In Uganda, unmet need crept up from 33.2 percent in 2000-01 to 33.8 percent in 2011 among sexually active, unmarried women age 15-24. At the same time, the small increase hides divergent trends in the two age groups (see Appendix Table A6). There was an overall increase in unmet need among sexually active, unmarried women age 15-19 from 32.7 percent in 2000-01 to 38.6 percent in 2011—with an intervening sharp rise to 45.0 percent in 2006—however, unmet need declined overall among those age 20-24, from 33.9 percent in 2000-01 to 29.0 percent in 2011.

### **5.3.3 Latin America and Caribbean**

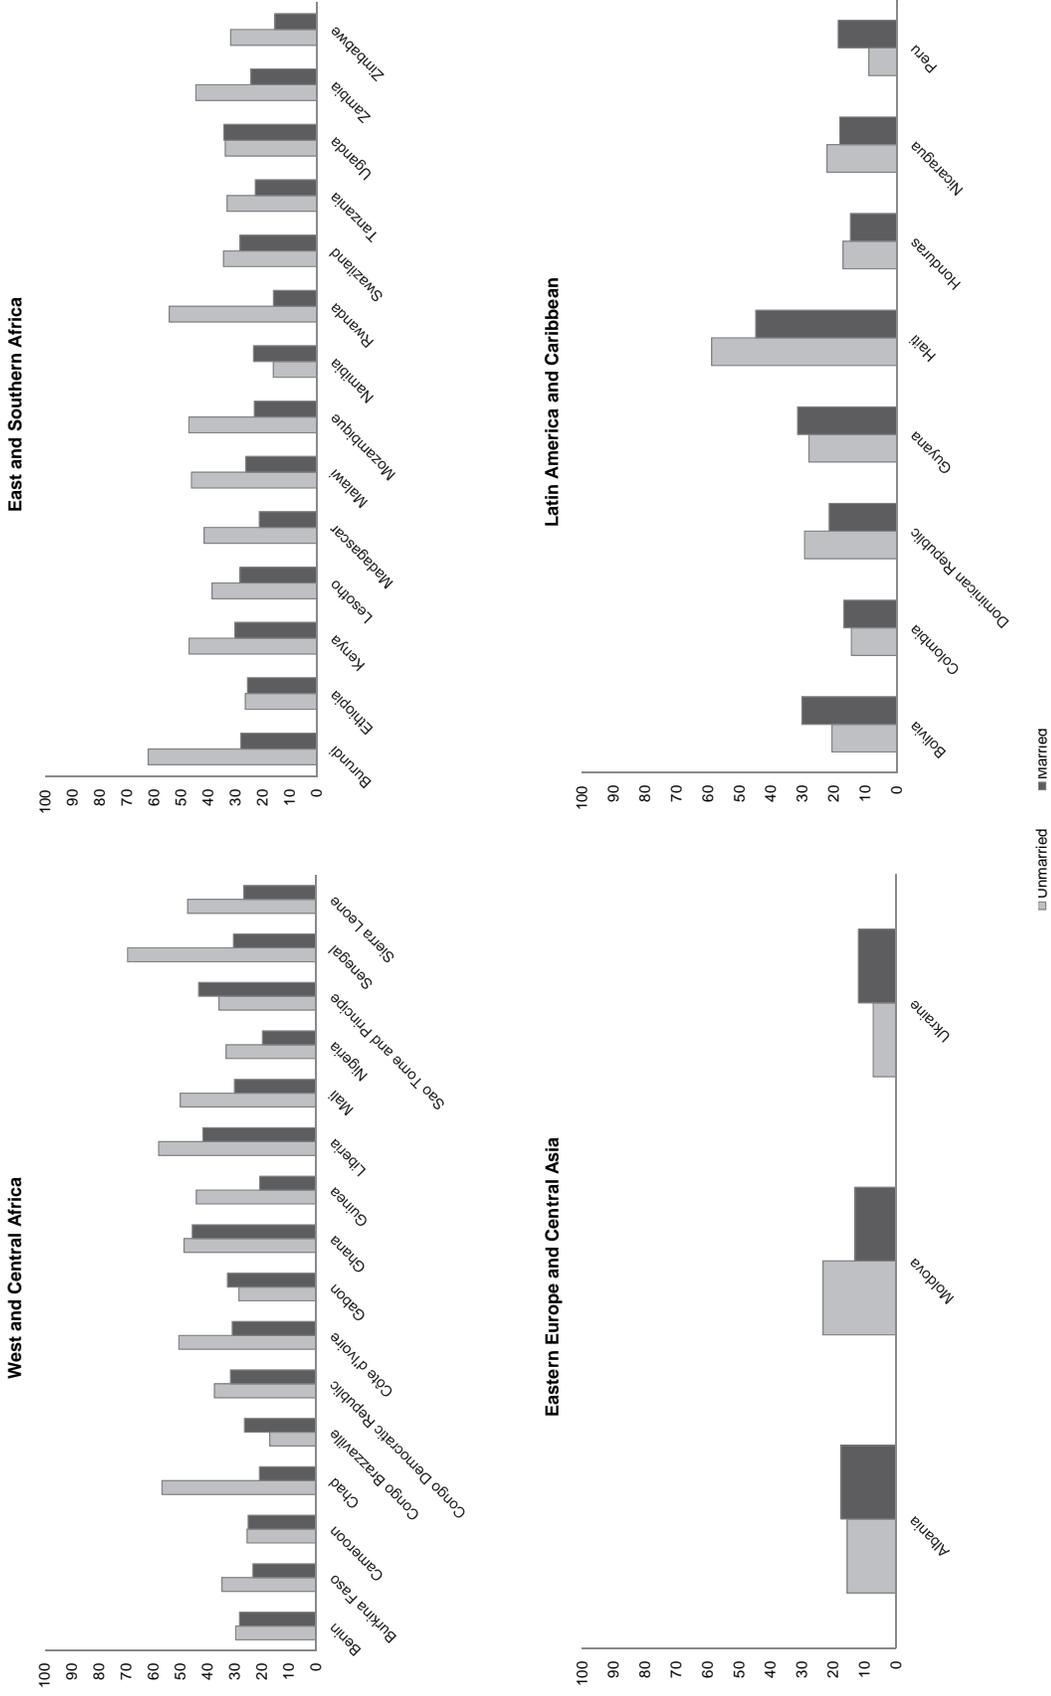

Demand for family planning has been steady and high in Latin America and the Caribbean, with the exception of Bolivia where it has been increasing. Unmet need has declined among sexually active, unmarried women age 15-24 in most countries and the pattern occurs in both age groups. Unmet need fell by 14 percentage points between 1998 and 2001 in Nicaragua and by more than eight percentage points between 2000 and 2010 in Peru. There was a modest one percentage point decline in Bolivia between 1998 and 2008 (from 21.7% to 20.6%), with an intervening sharp increase to 31.3 percent in 2003. Use of contraception has increased in this population over time as unmet need has declined.

Contrasting with the dominant trend, unmet need has increased slightly among sexually active, unmarried women age 15-24 in Colombia (from 10.7% in 2000 to 14.4% in 2010) and, to a larger extent, in Haiti (from 52.5% in 2000 to 58.8% in 2012). Use of contraception has declined by small degrees in both countries.

## **5.4 Comparison of Unmet Need among Young Unmarried and Young Married Women**

Figure 4 provides a comparison of unmet need among sexually active, unmarried women age 15-24 and married women the same age, by region, for all countries in which both populations were surveyed. Data come from the most recent survey in each country. In most regions, the predominant pattern is that of greater unmet need among unmarried women. The overall average is 35.9 percent for young unmarried women, compared with 25.9 percent for married women.

**Figure 4. Comparison of total unmet need for family planning between currently married women age 15-24 and unmarried, sexually active women age 15-24, most recent DHS surveys, 2000-2012**

#### **5.4.1 *West and Central Africa***

In West and Central Africa, unmet need is generally higher among sexually active, unmarried women age 15-24 than among married women age 15-24. Unmet need is, on average, almost 12 percentage points higher for young unmarried women. This pattern is not universal, however, with unmet need higher among married women in Congo (Brazzaville), Gabon, and São Tomé and Príncipe. Differences between the groups are negligible in Benin and Cameroon. Where differences are sizable, however, young unmarried women experience higher levels of unmet need than do young married women. Differences are particularly marked in Chad and Senegal (36 and 39 percentage points, respectively).

#### **5.4.2 *East and Southern Africa***

Sexually active, unmarried women age 15-24 also experience greater unmet need than married women in nearly all of the East and Southern African countries. Namibia and Uganda are the two exceptions, with unmet need higher among married women than among unmarried women. In Ethiopia, unmet need is similar across marital status. Differences by marital status, averaging 15 percentage points, are larger in East and Southern Africa compared with West and Central Africa: unmet need is 39.8 percent, on average, among young unmarried women and 24.8 percent among young married women. Larger differences occur in Rwanda (38 percentage points), Burundi (34 percentage points), Mozambique (24 percentage points), and Madagascar (20 percentage points), among other places.

#### **5.4.3 *Eastern Europe and Central Asia***

Differences by marital status are generally modest in the three Eastern Europe and Central Asia countries for which comparisons can be made. In Albania and Ukraine, unmet need is slightly higher among married women age 15-24, compared with sexually active, unmarried women the same age (about 2 percentage points higher in Albania and about 5 percentage points higher in Ukraine). Unmet need is higher by about 10 percentage points among sexually active, unmarried women age 15-24 in Moldova.

#### **5.4.4 *Latin America and Caribbean***

Patterns of unmet need by marital status are more varied in Latin America and the Caribbean. Unmet need among women age 15-24 is higher among sexually active, unmarried women in four countries but higher among married women in four countries. Differences may not be statistically significant in some countries. On average, unmet need is higher among young unmarried women (24.9%) than among young married women (24.5%)—a difference of just 0.4. Sexually active, unmarried women are more disadvantaged with regard to unmet need status in Haiti and the Dominican Republic, whereas married women are more disadvantaged in Bolivia and Peru.

## 6 Estimates of Young Women with Unmet Need

To estimate the numbers of women age 15-24 experiencing unmet need in the countries included in this study, DHS data on unmet need are combined with population estimates from the U.S. Census Bureau. Age- and sex-disaggregated population estimates for each of the countries, for the year of the most recent DHS survey in the country, were retrieved from the U.S. Census Bureau's International Database<sup>2</sup> on July 12, 2013, retaining only women age 15-19 and 20-24 (US Census Bureau 2012a). Details on the population estimation methods are described by the U.S. Census Bureau (US Census Bureau 2012b). For surveys that span two years, the population estimate is weighted according to the sample distribution of interviews conducted in each year, by age group. The population estimate in each age group is then multiplied by the DHS proportion of women reported to be a) married and b) unmarried and sexually active in the 30 days preceding the survey for each age group. These estimates for each age group and marital status are then multiplied by the DHS proportion with unmet need for family planning. Where the proportion of unmet need in a DHS survey is based on fewer than 25 unweighted cases, no estimate of the number of women with unmet need is calculated.

The resulting estimates of the number of women age 15-24 experiencing unmet need for family planning, by age group and marital status, are presented in Table 7. These estimates should be viewed as crude estimates of the number of young women with unmet need in each country in that they rely on the accuracy of both the underlying population estimate and the reported marital and need status. The proportion of young women who are unmarried and sexually active may be especially subject to underreporting due to social desirability bias, particularly in cultural settings where nonmarital sexual activity is not socially sanctioned. Thus, the estimates presented here are believed to be conservative estimates of the actual number of women with unmet need.

In total, it is estimated that nearly 33 million women age 15-24 have an unmet need for family planning in the 61 countries surveyed by DHS. Sixty-four percent of young women with unmet need—68 percent of young married women with unmet need—reside in one of the 10 South and Southeast Asian countries, 16 percent are in West and Central Africa (18 countries), and 12 percent are in East and Southern Africa (15 countries).

The first observation to make in comparing young women by marital status (for those countries with data on both populations) is that, nearly everywhere, there is a greater number of married women age 15-24 with unmet need than sexually active, unmarried women in this age range. This is despite a larger percentage of sexually active, unmarried women experiencing unmet need compared with their married counterparts in most countries. The difference reflects the relatively large proportion of women of this age who are married and the small proportion who are unmarried and sexually active. There are several exceptions to this pattern among women in the younger age group (15-19) in Africa (Côte d'Ivoire, Gabon, Liberia, Sierra Leone, Namibia, Rwanda, Swaziland, and Tanzania). However, where this is the case, the pattern is reversed among women in the older age group (20-24). For example, in Côte d'Ivoire there are about twice as many sexually active, unmarried women age 15-19 with unmet need as there are married women with unmet need, but at the same time, there are about twice as many married women age 20-24 with unmet need as there are sexually active, unmarried women in this older age group.

Notes:

<sup>1</sup>For surveys that span two years, population estimate is weighted according to the sample distribution of interviews conducted in each year, by age category.

<sup>2</sup>Source for estimates of the female population age 15-19 and 20-24: US Census Bureau, downloaded July 12, 2013 from <http://www.census.gov/population/international/data/idb/informationGateway.php>

<sup>3</sup>DHS survey estimates of the proportion married, or proportion unmarried and sexually active, and proportion with unmet need for family planning, by age category, are applied to the population estimates to estimate the number of women of each age category and marital status who experience unmet need for family planning.

<sup>4</sup>No estimates are made for countries in which the DHS survey collected data from ever-married women only. An asterisk indicates that the estimate is based on fewer than 25 unweighted cases and has been suppressed.

Similarly, there are more women age 20-24 than women age 15-19 with unmet need for family planning in all regions, with the exception of Eastern Europe and Central Asia. In Eastern Europe and Central Asia the age pattern of unmet need is driven by Turkey, which is not only the most populous country in the region but also the country with the largest number of young women experiencing unmet need. In Turkey, an estimated 700,000 women age 15-19 experience unmet need compared with 500,000 women age 20-24. In no other country in the region is this pattern observed. Only four other countries in the study have greater numbers of women age 15-19 with unmet need than women age 20-24: Madagascar, Bangladesh, the Maldives, and Vietnam.

## 7 Age and Unmet Need

This study examines two questions related to unmet need for family planning and age. First, among young women (age 15-24), do the youngest women experience higher or lower levels of unmet need than slightly older young women? Second, how do young women (age 15-19 and 20-24) compare with women older than age 25 regarding unmet need?

### 7.1 Age and Unmet Need among Young Married Women

Table 8, which presents levels of unmet need among married women age 15-24 in *two-year age groups*, answers the first question. Estimates are not provided for unmarried women because the unweighted number of sexually active, unmarried women under age 25 is insufficient in most surveys to support such fine levels of disaggregation.

These data indicate that in Eastern Europe and Central Asia, South and Southeast Asia, and Latin America and the Caribbean unmet need is generally highest among the youngest women, i.e., those age 15-16, and declines with age. Most countries in these regions exhibit this pattern fairly consistently, although there are some exceptions (e.g., Kyrgyz Republic and Indonesia). East and Southern Africa, on average, depicts a similar pattern: unmet need is highest among women age 15-16 (28.7%) and consistently lower, about 25 percent, in subsequent age groups. The lowest level of unmet need in East and Southern Africa is among women age 19-20 (24.0%). Many, but not all, of the countries in this region show this pattern.

In contrast to the regions discussed above, unmet need in the Middle East and North Africa *increases with age*. Levels of unmet need are more dynamic in West and Central Africa and do not resemble either the other regional patterns. Rather, the distribution of unmet need in West and Central Africa approximates that of a normal curve, peaking among women age 19-20 (30.6%). The individual countries that make up the region exhibit substantial variation in the age distribution of unmet need among young married women age 15-24.

**Table 8. Unmet need for family planning among currently married women age 15-24, by two-year age group, most recent DHS surveys, 2000-2012**

		n	<b>1,074</b>	<b>2,612</b>	<b>4,238</b>	<b>5,045</b>	<b>5,869</b>	<b>18,838</b>

Note: Figures in parentheses are based on 25-49 unweighted cases. An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed. The reported n is the weighted number of cases.

Table 9 (see below) indicates that unmet need is higher among married women age 15-19 than among married women age 20-24 in all regions except the Middle East and North Africa, where the converse is true. The largest differences are found in Latin America and the Caribbean where the two age groups are separated by almost eight percentage points.

## 7.2 Comparison of Unmet Need between Younger and Older Married Women

To address the second question about age and unmet need, Table 9 compares unmet need among married women age 15-24 with unmet need among married women age 25-49. Women age 15-24 are further disaggregated into two five-year age group (15-19 and 20-24). Because the focus of this study is young women, women age 25-49 are not disaggregated further. However, Appendix Table A7 provides the age distribution of unmet need among married women age 15-49, by five-year age group, for all the countries with DHS surveys included in the study.

**Table 9. Comparison of unmet need for family planning among currently married women age 15-24 and age 25-49, most recent DHS surveys, 2000-2012**

Note: The reported n is the weighted number of cases.

Table 9 indicates that, in every region with the exception of the Middle East and North Africa, married women age 15-24 experience higher levels of unmet need, compared with married women age 25 and older. Again, the largest differences between the two age groups are in Latin America and the Caribbean where married women age 15-24, on average, experience levels of unmet need more than six percentage points higher than married women age 25-49. Differences are also substantial in Eastern Europe and Central Asia, South and Southeast Asia (each nearly four percentage points difference), and West and Central Africa (more than three percentage points difference). The pattern is reversed in the Middle East and North Africa, with unmet need almost two percentage points higher among married women age 25-49 than among those age 15-24.

### **7.2.1 *West and Central Africa***

Married women age 15-24 experience greater unmet need than their older counterparts age 25-49 in 13 West and Central African countries. The converse is the case in the remaining five countries (Burkina Faso, Guinea, Niger, Nigeria, and Sierra Leone), although the differences are small and unlikely to be statistically significant in most places. Where differences are sizeable, unmet need is greater among younger women (age 15-24). This pattern applies to Congo (Brazzaville), Democratic Republic of Congo, Gabon, Ghana, Liberia, and São Tomé and Príncipe.

### **7.2.2 *East and Southern Africa***

East and Southern Africa exhibits more diverse patterns of unmet need when younger married women (age 15-24) and older married women (age 25-49) are compared. Unmet need is the same high level for both age groups in Uganda and Malawi and the levels are similar in Ethiopia and Zimbabwe. Unmet need is higher among married women age 15-24 in Eritrea, Kenya, Lesotho, Madagascar, Swaziland, and Namibia, but higher among married women age 25-49 than those younger than 25 in Burundi, Mozambique, and Rwanda and, by a smaller margin, in Tanzania and Zambia.

### **7.2.3 *Middle East and North Africa***

There is virtually no difference in unmet need between married women age 15-24 and those age 25-49 in Jordan. However, in Egypt and Morocco, older married women (age 25-49) experience higher levels of unmet need than younger women—more than 3 percentage points higher in Egypt and just over two percentage points higher in Morocco.

### **7.2.4 *Eastern Europe and Central Asia***

The age pattern for unmet need in Eastern Europe and Central Asia is consistent. In all countries, unmet need is higher among young married women age 15-24 compared with those age 25-49. The differences are largest in Turkey—where unmet need among younger women (16.2%) is double that of older women (8.1 %)—and in Armenia and Albania. There is only a slight difference in unmet need between age groups in Azerbaijan (15.9% versus 15.3%).

### **7.2.5 *South and Southeast Asia***

Generally, younger married women in South and Southeast Asia typically experience higher levels of unmet need—almost four percentage points higher, on average—than older married women. This pattern is not uniform, but occurs in seven of 10 countries in the region. Differences are particularly striking in Nepal and India, where younger married women experience levels of unmet need substantially

higher than their older counterparts—16 percentage points higher in Nepal and more than 12 percentage points higher in India. In contrast to this predominant pattern, unmet need in Cambodia is more than seven percentage points higher among married women age 25-49 than among those age 15-24. Likewise, older married women in Indonesia have somewhat higher unmet need than younger married women. In Pakistan, levels of unmet need are nearly identical for the two age groups.

### **7.2.6 *Latin America and Caribbean***

As with Eastern Europe and Central Asia, unmet need is universally higher among married women age 15-24 than among married women age 25-49 in Latin America and the Caribbean. Furthermore, these differences are frequently sizable, ranging from more than 13 percentage points in the Dominican Republic to just under four percentage points in Guyana. Bolivia, Colombia, the Dominican Republic, Haiti, and Peru all have levels of unmet need among younger married women age 15-24 that exceed levels among older married women age 25-49 by nearly 10 percentage points or more.

## 8 Factors Associated with Unmet Need

### 8.1 Unmet Need and Place of Residence among Young Married and Unmarried Women

Table 10 displays levels of unmet need among married women age 15-24 and sexually active, unmarried women age 15-24, by urban and rural residence. Differences between women living in urban areas and those living in rural areas that are statistically significant, as indicated by a Wald test of independence, are so indicated by a double asterisk (\*\*).

In nearly all regions and for both married and unmarried women age 15-24, unmet need is higher, on average, among rural women than among urban women. The differences are greatest among *sexually active, unmarried women* in East and Southern Africa, West and Central Africa, and in Latin America and the Caribbean. In these regions, women in rural areas experience levels of unmet need more than 10 percentage points higher than their urban counterparts. At the same time, levels of unmet need among *married women* in West and Central Africa are higher on average among women in urban areas (32.3%) than among those in rural areas (28.2%). For the three countries in Eastern Europe and Central Asia with data on sexually active, unmarried women, unmet need averages more than five percentage points higher among women in urban areas (17.4%) than those in rural areas (11.9%).

#### 8.1.1 West and Central Africa

Unmet need differs significantly by place of residence in the majority of countries in West and Central Africa; these include 11 of 18 countries with data on married women age 15-24 and nine of 16 countries with data on sexually active, unmarried women age 15-24. Differences are usually statistically significant for women of both marital statuses within each country. However, unmet need is significant in Liberia only among sexually active, unmarried women, and in Ghana and Senegal, only among married women. Where unmet need differs significantly by place of residence among *sexually active, unmarried women* age 15-24, rural women are consistently more disadvantaged than their urban counterparts. Among *married women* age 15-24, unmet need is significantly higher among urban women than rural women in seven of the 11 countries in which differences are significant.

#### 8.1.2 East and Southern Africa

Compared with West and Central Africa fewer countries in East and Southern Africa show significant differences in unmet need by place of residence. Among *married women* age 15-24, unmet need is higher for rural women in Ethiopia, Namibia, Tanzania, and Zambia while it is higher for urban women in Burundi and Eritrea. The differences are greatest in Ethiopia (more than 12 percentage points) and Namibia (more than 10 percentage points).

Among *sexually active, unmarried women* age 15-24, unmet need is higher for rural women in Malawi, Mozambique, and Namibia. The differences tend to be greater for unmarried women than for married women. In Namibia the difference in unmet need is 13.6 percent for unmarried women compared with 10.7 percent for married women; in Malawi the difference is 20.5 percent for unmarried women compared with 3.9 percent for married women.

#### 8.1.3 Middle East and North Africa

Estimates suggest levels of unmet need among married women age 15-24 do not differ significantly by place of residence in any of the three Middle East and North Africa surveys providing data to this study.

Table 10. Unmet need for family planning among women age 15-24, by urban-rural residence, most recent DHS surveys, 2000-2012

\*\* Wald test of independence significant at p<0.05

### **8.1.4 Eastern Europe and Central Asia**

The only country in Eastern Europe and Central Asia where differences in unmet need by place of residence are statistically significant is Azerbaijan. Here, unmet need is more than five percentage points higher among rural married women age 15-24 than among urban married women the same age, 18.4 percent and 12.9 percent, respectively.

### **8.1.5 South and Southeast Asia**

Unmet need differs significantly by place of residence in four of the 10 countries in South and Southeast Asia: Bangladesh, Cambodia, Indonesia, and Nepal. In each country, married women age 15-24 living in rural areas experience greater unmet need than their urban counterparts. These differences are particularly notable in Nepal where the level of unmet need among rural married women is 40.6 percent compared with 28.1 percent among urban married women, a difference of more than 12 percentage points.

### **8.1.6 Latin America and Caribbean**

In two countries in Latin America and the Caribbean, Bolivia and Peru, levels of unmet need are significantly higher in rural areas compared with urban areas for both married and unmarried women age 15-24. In a third country, Nicaragua, unmet need is significantly higher in rural areas for married women only (nearly two percentage points higher). This difference among married women in Peru is more than six percentage points and in Bolivia the difference is more than 14 percentage points. The gap is even wider among *sexually active, unmarried women* age 15-24: more than 16 percentage points higher among those living in rural areas in Peru and more than 20 percentage points higher among those living in rural areas in Bolivia.

## **8.2 Unmet Need and Household Wealth among Young Married Women**

Table 11 presents levels of unmet need among married women age 15-24 by household wealth quintile (lowest (poorest) quintile, second quintile, middle quintile, fourth quintile, highest (richest) quintile). As with subsequent socio-demographic characteristics, there are too few cases to disaggregate data for sexually active, unmarried women age 15-24 so only data for married women are presented. Differences by wealth quintile that are statistically significant—as indicated by a Wald test of independence—are marked with a double asterisk (\*\*). In nearly all regions, unmet need decreases with increasing wealth quintile. The pattern is less clear in West and Central Africa, where unmet need is highest among women in the highest (richest) quintile—followed by women in the middle and second quintiles—and unmet need lowest among women in the fourth and lowest (poorest) quintiles.

### **8.2.1 West and Central Africa**

Unmet need among married women age 15-24 differs significantly by wealth status in eight of 18 West and Central African countries. In Guinea, Mali, Niger, and Nigeria, unmet need is highest among women in the higher (richer) quintiles (or richest and richer), and lower among women in lower (poorer) wealth quintiles those in the poorer quintiles. However, in Ghana the pattern is reversed, with unmet need highest among women in lower wealth quintiles. Benin and Cameroon indicate unmet need is higher close to the middle of the wealth distribution, while Chad suggests a bimodal distribution with high levels of unmet need in the middle quintile and in the richest quintile.

Table 11. Unmet need for family planning among currently married women age 15-24, by wealth quintile, most recent DHS surveys, 2000-2012

### **8.2.2 East and Southern Africa**

The six countries in East and Southern Africa for which unmet need differs significantly by wealth suggest a negative association: unmet need declines with household wealth quintile. This pattern is evident in Ethiopia, Kenya, and Uganda. However, unmet need suggests a U-shaped distribution in Madagascar, with higher levels of unmet need in the lowest (poorest) and highest (richest) quintiles. In Mozambique, unmet need increases with increasing wealth quintile.

### **8.2.3 Middle East and North Africa**

Egypt is the only country in the Middle East and North Africa region where levels of unmet need vary significantly by wealth quintile among married women age 15-24. Here, unmet need declines steadily as wealth quintiles increase, from 13.2 percent in the lowest wealth quintile to 3.9 percent in the highest.

### **8.2.4 Eastern Europe and Central Asia**

In Azerbaijan, Turkey, and the Ukraine, unmet need among married women age 15-24 declines consistently with increasing wealth quintiles. The differences are largest in Azerbaijan and Ukraine. In Azerbaijan, unmet need is 27.5 percent in the lowest wealth quintile and 9.6 percent in the highest wealth quintile. In Ukraine, these figures are 20.6 percent and 3.6 percent, respectively.

### **8.2.5 South and Southeast Asia**

Unmet need among married women age 15-24 in South and Southeast Asia differs significantly by wealth status in just two of the 10 countries: India and Indonesia. In both these countries, unmet need is highest among women in the lowest wealth quintile (24.5 percent in India and 11.0 percent in Indonesia) and declines with subsequent wealth quintiles. However, in Indonesia, unmet need increases again in the richest wealth quintile (10.1%) to a level near that in the lowest wealth quintile.

### **8.2.6 Latin America and Caribbean**

In Bolivia, Colombia, and Guyana, unmet need declines consistently among married women age 15-24 from the lowest to the highest wealth quintile. The differences are statistically significant and quite substantial. In all three countries, levels of unmet need among young married women in the highest wealth quintile are about half that of unmet need among young married women in the lowest wealth quintile. In the case of Bolivia and Guyana, the differences are about 20 percentage points; in Colombia, the difference is about 10 percentage points.

## **8.3 Unmet Need and Education among Young Married Women**

Table 12 indicates levels of unmet need among married women age 15-24 by educational attainment. As with prior tables showing unmet need by socio-demographic characteristics, a double asterisk (\*\*) indicates a significant Wald test of independence. Differences in unmet need by education are statistically significant in the majority of countries in all regions except East and Southern Africa and South and Southeast Asia, where only about one-third of countries show these differences to be statistically significant.

\*\* Wald test of independence significant at  $p < 0.05$

### **8.3.1 West and Central Africa**

Unmet need among married women age 15-24 differs by educational attainment in 12 of 18 countries in West and Central Africa. On average, unmet need increases with education through completion of secondary schooling. This pattern is observed for most countries that show statistically significant differences in unmet need by level of education. However, unmet need decreases with education in Burkina Faso; and in Liberia, Mauritania, and Senegal, unmet need is higher among young married women with primary education than among either those with no education or those with secondary education.

### **8.3.2 East and Southern Africa**

The patterns of unmet need by level of education are just as varied in East and Southern Africa as in West and Central Africa. Unmet need among married women age 15-24 increases with educational attainment in Eritrea and Mozambique, declines with educational attainment in Ethiopia and Swaziland, and peaks among women with primary education in Uganda. In no other countries is educational attainment significantly associated with unmet need in this population.

### **8.3.3 Middle East and North Africa**

Among married women age 15-24 in both Egypt and Jordan, unmet need declines as educational attainment increases. In Egypt the decline is from 12.0 percent among women with no education to 6.1 percent among women with higher education. The decline in Jordan is from 25.1 percent among women with primary education to 6.6 percent among women with higher education.

### **8.3.4 Eastern Europe and Central Asia**

Educational attainment is significantly associated with unmet need among married women age 15-24 in five of seven Eastern Europe and Central Asia countries. In each of the five countries, unmet need decreases with increasing level of education. In contrast to most of the other regions, countries in Eastern Europe and Central Asia typically have few married women age 15-24 with no education or only primary education. As a result, statistical analysis of unmet need by educational attainment is largely restricted to women achieving secondary and higher education.

### **8.3.5 South and Southeast Asia**

Educational attainment is significantly associated with unmet need among married women age 15-24 in just three of 10 countries in South and Southeast Asia: Indonesia, Nepal, and Vietnam. While unmet need declines with increasing educational attainment across the region as a whole, these three countries show diverse patterns. In Indonesia, unmet need is *highest* among women with no education (19.5%) and those with higher education (10.1%); it is *lowest* among women with primary education (7.7%) and those with secondary education (7.6%). Vietnam is similar, with unmet need *highest* among those with no education (14.3%) and those with secondary education (12.4%); it is *lowest* among those with primary education (7.8%). Nepal shows an opposing pattern: unmet need is higher among women with primary education (42.1%) or secondary education (43.2%) than among women with no education (31.2%) or higher education (37.2%).

### **8.3.6 Latin America and Caribbean**

In five of eight countries in Latin American and the Caribbean, educational attainment is significantly associated with unmet need among married women age 15-24. Unmet need declines quite

consistently with increasing level of education in Bolivia, Colombia, the Dominican Republic, Nicaragua, and Peru. Two small variations to this general pattern are evident. In the Dominican Republic, the *lowest* level of unmet need is among women with no education (13.1%); the *highest* level is among women with primary education (26.3%); thereafter unmet need decreases with increasing level of education. In Nicaragua, unmet need decreases with increasing level of education, from 23.8 percent among women with no education to 15.5 percent among women with secondary education, then increases sharply to 21.8 percent among women with higher education.

#### 8.4 Unmet Need and Parity among Young Married Women

Table 13 displays levels of unmet need among married women age 15-24 by parity. Women are disaggregated according to four parity categories: parity 0 (nulliparous), parity 1 (1 birth), parity 2 (2 births), and parity 3+ (3 or more births). Differences across parity categories that are statistically significant—as indicated by a Wald test of independence—are marked with a double asterisk (\*\*). The results indicate that parity is significantly associated with unmet need in a majority of countries in most regions, and in approximately half of the countries in Eastern Europe and Central Asia and in Latin America and the Caribbean.

\*\* Wald test of independence significant at  $p < 0.05$

#### 8.4.1 West and Central Africa

Unmet need differs significantly by parity among married women age 15-24 in 13 of 18 countries in West and Central Africa. In all 13 countries, unmet need increases with parity. The largest differences are between women with no births (nulliparous women) and women with one or more births. Unmet need does not always increase across parity categories after parity 1, but may *plateau* at levels higher than nulliparous women, or may decline slightly among women with three or more births (parity 3+), as in Burkina Faso and Chad.

#### 8.4.2 East and Southern Africa

Unmet need among married women age 15-24 differs significantly by parity in nine of 15 countries in East and Southern African. In each country, unmet need increases with parity and—as in West and Central Africa—the largest differences are seen in the comparison of nulliparous women (parity 0) and women with one birth (parity 1). For example, unmet need among nulliparous women in Burundi

is just 5.2 percent, compared with 30.7 percent among women with one birth, a difference of more than 25 percentage points. The phenomenon of “plateauing” levels of unmet need at parity 1 and higher that is seen in West and Central Africa, however, is not apparent in East and Southern Africa. Unmet need continues to rise steadily (though by smaller degrees), as parity increases from parity 1 to parity 3+.

#### **8.4.3 Middle East and North Africa**

Unmet need increases with parity in Egypt and Jordan, with the biggest increases occurring between nulliparous women (0.5% and 3.1%, respectively) and women with one birth (11.0% and 18.9%), as in the other regions. In Jordan, unmet need is *lower* among women with two births (14.9%) than among either women with one birth (18.9%) or women with three or more births (20.1%).

#### **8.4.4 Eastern Europe and Central Asia**

Unmet need among married women age 15-24 is significantly associated with parity in only three of seven countries Eastern Europe and Central Asia; the patterns exhibited by the three countries—Azerbaijan, Moldova, and the Ukraine—are diverse. Unmet need increases with parity in both Azerbaijan and Ukraine. Although in Azerbaijan there is a large difference between women with no births (4.8%) and women with one birth (18.9%), the difference in Ukraine is more modest (9.0% and 12.3%, respectively). In Moldova, women who are parity 0, parity 1, and parity 2 experience similar levels of unmet need (12.5%, 13.1%, and 12.3%, respectively).

#### **8.4.5 South and Southeast Asia**

In eight of 10 countries in South and Southeast Asia—Nepal and Vietnam are exceptions—unmet need among married women age 15-24 is significantly associated with parity. In the eight countries, unmet need is consistently *lower* among nulliparous women than among women of other parities. However, the patterns of unmet need across parity categories 1, 2, and 3+ are more varied than those seen in other regions. In Bangladesh, Indonesia, and Pakistan, unmet need increases steadily with parity. The relatively large difference between parity 0 women and parity 1 women that is apparent in most countries is absent in Bangladesh. Instead, unmet need in Bangladesh increases almost monotonically by approximately three percentage points between each parity category.

In Cambodia, India, and the Philippines, unmet need is higher among parous women than among nulliparous women; however, as was the case in Jordan, unmet need is lower among parity 2 women than among parity 1 women or parity 3+ women. In the Maldives and Timor-Leste, unmet need rises sharply between parity 0 (nulliparous) women and parity 1 women, then declines and as parity increases.

#### **8.4.6 Latin America and Caribbean**

Unmet need is significantly associated with parity among married women age 15-24 in four of the eight Latin American and Caribbean countries for which data are available: Bolivia, Colombia, Guyana, and Peru. In Guyana, large increases in unmet need (about 10 percentage points) are seen across each parity category. In the other three countries (Bolivia, Colombia, and Peru) a new pattern of unmet need emerges that is not observed in the other regions. In Bolivia, Colombia, and Peru, unmet need is highest among nulliparous women (parity 0), then drops sharply among primiparous women (parity 1); thereafter, it increases gradually with parity.

## 9 Components of Unmet Need

Unmet need for family planning is somewhat unusual as a demographic indicator in that it is a composite indicator with both attitudinal and behavioral components. This section of the study unpacks and explores the various components underlying the indicator among women age 15-24, with the aim of expanding our insight into the unmet need indicator, itself.

The indicator is first applied to the *population of women at risk of pregnancy*, either because they are married (and who are, therefore, assumed to be sexually active) or unmarried women who explicitly report they were sexually active in the past 30 days. Tables 14 and 15 present current levels and trends in the proportion of women age 15-24 who are first married by age 15 and by age 18. Tables 16 and 17 provide current levels and trends in the proportion of unmarried women age 15-24 who are sexually active.

Next, young women's need for family planning is established by *women's reports of current fertility intentions*. Women who want a child within the next two years are categorized as having *no need* for family planning; women who want a child after two or more years are categorized as having a *need for spacing*; and, women who want no (more) children are categorized as having a *need for limiting*. Two aspects of fertility desires are explored in this report: 1) ideal number of children and 2) desire for a(nother) child. Tables 18 and 19 display the current levels and trends in the percent distribution and mean ideal number of children desired by married women age 15-24; Tables 20 and 21 show these data for unmarried women age 15-24. While the ideal number of children is not necessarily static over the entire life course—because, over time, an individual woman may change her mind about the number of children she would like to have—this indicator is a useful description of the fertility regime to which cohorts of young women aspire. Tables 22-25 present the percent distribution of desires for a(nother) child, which is the specific survey item used in the algorithm for the unmet need indicator. As in previous tables, current levels and trends are presented separately for married women and sexually active, unmarried women.

Lastly, *current use of contraception* among young women age 15-24 is the indicator used to determine whether need for family planning is “met” or remains “unmet.” Tables 26-29 provide data on current use of contraception by method type, for both married women and sexually active, unmarried women age 15-24. Levels and trends in current use of contraception are presented separately for married women and sexually active, unmarried women.

### 9.1 Exposure to the Risk of Pregnancy through Marriage

Table 14 presents the proportion of women age 15-24 who experience their first marriage or union by age 15 and by age 18. The *highest* proportions of women married or in union by these two ages are in West and Central Africa, followed by Latin America and the Caribbean, East and Southern Africa, and South and Southeast Asia. The *lowest* proportions of women married or in union by age 15 and by age 18 are in the Middle East and North Africa and in Eastern Europe and Central Asia. Table 15 shows trends in the proportion of women age 15-24 first married or in union by age 15 and by age 18 for countries with multiple DHS surveys. The results indicate that, overall, the proportions of young women marrying by age 15 or by age 18 have decreased over time in most regions, although these trends are not universal in Latin America and the Caribbean or in East and Southern Africa. This finding means that the proportion of young women who are at risk of unmet need (or met need) through marriage is declining. This trend may be offset, in whole or part, if the proportion that is sexually active among unmarried young women is sizable and/or increasing.

### 9.1.1 West and Central Africa

In the 18 countries in West and Central Africa for which data are available, an average of 39.2 percent of women age 15-24 are married by age 15; this is the *highest proportion among all the regions* (Table 14). Within West and Central Africa, this proportion ranges from a low of 19.1 percent among women age 15-24 in São Tomé and Príncipe to a high of 67.6 percent in Niger. Nearly three-quarters (73 percent) of women age 20-24 are married by age 18, with proportions ranging from 56.1 percent in Gabon to 91.8 percent in Niger.

Table 15 shows trends in age at marriage (by age 15 and by age 18) among women age 15-24 in 13 countries in West and Central Africa that have multiple DHS surveys. The general trend is toward decreasing proportions of young women marrying by age 15. The largest changes are seen in Niger and Côte d'Ivoire: the proportion marrying by age 15 in Niger decreased from 78.8 percent to 67.6 percent and in Côte d'Ivoire the proportion decreased from 39.3 percent to 31.8 percent. The opposite trend is seen in Chad and Congo (Brazzaville) where the proportion of young women marrying by age 15 among 15-24 year olds has increased (from 53.5 percent to 58.6 percent in Chad and from 22.9 percent to 28.4 percent in Congo, Brazzaville).

Trends in the proportion of women age 20-24 marrying by age 18 largely mirror trends for women age 15-24 marrying by age 15. These proportions have decreased in the majority of countries in the region. In contrast, the proportions marrying by age 18 and by age 15 have increased in Chad and

Congo (Brazzaville). A different scenario emerges in Guinea and Nigeria where the proportion marrying by age 15 has declined over time while the proportion marrying by age 18 has increased. This pattern suggests a shift away from the earliest marriages, but not out of adolescence altogether.

### **9.1.2 East and Southern Africa**

In East and Southern Africa more than 20 percent of women age 15-24 (22.9%) are married by age 15. While marriage this early is rare in Rwanda (4.4 percent), Swaziland (9.4 percent), and Burundi (9.9 percent), it exceeds 40 percent in Eritrea and Ethiopia (Table 14). On average, nearly 60 percent of women age 20-24 (59.8%) are married by age 18 in the region. The proportion ranges from less than one-third of women age 20-24 in Rwanda (30.4%) to more than three-quarters of women in Eritrea (76.6%).

Compared with West and Central Africa, there is not as clear a trend away from early marriage in East and Southern Africa. A larger number of countries in East and Southern Africa have increasing proportions of women marrying by age 15 or by age 18 over time (Table 15). The proportion of women age 15-24 marrying by age 15 and the proportion of women age 20-24 marrying by age 18 have declined in six countries and increased in six countries, with the two proportions almost always moving in the same direction. However, in Tanzania, the proportion marrying by age 15 has declined modestly while the proportion marrying by age 18 has increased slightly (after a large increase in 2004-05). In Zambia, the proportion marrying by age 15 in 2007 is nearly the same as it was in 1996, while the proportion marrying by age 18 has declined more than four percentage points during the same period.

### **9.1.3 Middle East and North Africa**

Early marriage is uncommon in the three countries representing the Middle East and North Africa: Egypt, Jordan, and Morocco. On average, only 13.4 percent of women age 15-24 are married or in union by age 15 (Table 14), although the percentage in Morocco (19.1%) is nearly double that of Egypt (10.7%) or Jordan (10.3%). At the same time, nearly half (48.8%) of women age 20-24 have married by age 18. There is less variation among the three countries in the proportion marrying by age 18, which ranges from 43.1 percent in Jordan to 55.6 percent in Morocco. Table 15 shows that there has been a decline over time in the proportion of women age 15-24 marrying by age 15 and the proportion of women age 20-24 marrying by age 18 in both Egypt and Jordan. These proportions have increased in Morocco.

### **9.1.4 Eastern Europe and Central Asia**

The Eastern Europe and Central Asia region has the *lowest proportion of young women who were first married by age 15 or age 18*. On average, only 6.1 percent of women age 15-24 in this region are married by age 15 (Table 14). The range is from less than two percent in the Kyrgyz Republic (1.1%) and Armenia (1.2%) to 13.4 percent in Turkey. More than one-third (39.4%) of women age 20-24 are married by age 18; again, this is the lowest proportion of all the regions. The proportion married by age 18 ranges from 30.6 percent in Armenia to 50.9 percent in Turkey. Table 15 shows that there has been a decline over time in the proportion of young women marrying by age 15 and by age 18 in the three countries for which multiple DHS surveys are available—Armenia, Kyrgyz Republic, and Turkey.

### **9.1.5 South and Southeast Asia**

Among the countries in South and Southeast Asia included in this study an average of 20.6 percent of women age 15-24 are married by age 15 (Table 14). The proportion ranges from 1.4 percent in the Maldives to more than half of women age 15-24 in Bangladesh (52.9%). Only in the Maldives and Vietnam are less than 10 percent of young women married by age 15. On average, more than half of

women age 20-24 (54.3%) are married by age 18. The proportion ranges from 40.8 percent in Vietnam to 85.9 percent in Bangladesh.

The proportion marrying by age 15 and by age 18 has declined over time in every country in South and Southeast Asia (Table 15). Some of the steepest declines are in this region, suggesting a rapid shift away from early marriage.

### **9.1.6 Latin America and Caribbean**

Marriage at a young age is common in Latin America and the Caribbean. Table 14 shows that nearly three in 10 women age 15-24 (27.9%) are married or in union by age 15. This proportion ranges from 18.1 percent in Peru to 42.1 percent in the Dominican Republic. On average, 61.2 percent of women age 20-24 have married by age 18; the range extends from 50.1 percent in Guyana to 76.9 percent in Nicaragua.

Trends over time in age at marriage vary among young women in Latin America and the Caribbean (Table 15). The proportion married or in union by age 15 among women age 15-24 has increased in Bolivia, Colombia, and the Dominican Republic. In these same countries, the proportion married or in union by age 18 among women age 20-24 has declined in Colombia, stayed the same in Bolivia—after a sizable increase in 2003—and increased in the Dominican Republic. The proportion married by age 15 and the proportion married by age 18 both declined in Haiti, Honduras, Nicaragua, and Peru. In Haiti, the decline in the proportion married by these ages between the 2000 survey and the most recent survey in 2012 was interrupted by an increase in the 2005-06 survey, before falling sharply to levels below 2000 in the 2012 survey.

## **9.2 Exposure to the Risk of Pregnancy through Sexual Activity outside of Marriage**

Table 16 indicates the proportion of all unmarried women age 15-24, by five-year age group, who report being sexually active in the past 30 days. The data are from 41 countries with samples of never-married women. Table 17 demonstrates trends in the proportion of unmarried women age 15-24 who report being sexually active in the past 30 days. The data are from 29 countries with multiple DHS surveys that include never-married women. As mentioned previously, social desirability bias may result in an underreporting of sexual activity among unmarried women and this bias may be larger among the youngest women and in settings with the most conservative norms regarding gender and premarital sexual activity. A further consideration is that these norms, and hence, social desirability bias, are subject to change over time, potentially making it difficult to discern whether a *change in reported levels of sexual activity* represents *actual change in sexual activity* or a change in inclination to report the behavior. Therefore, the estimates of sexual activity among unmarried women age 15-24 presented in Table 16 should be regarded as conservative estimates. Likewise, the observed trends in sexual activity among unmarried women age 15-24 reported in Table 17 should be interpreted with caution.

On average, the proportion of unmarried women age 15-24 who are sexually active is *highest* in West and Central Africa (18.8%) and *lowest* in East and Southern Africa (9.7%). The proportion is similar in Eastern Europe and Central Asia (12.3%) and Latin America and Caribbean (12.8%). No data on this indicator is available for countries in the Middle East and North Africa or South and Southeast Asia.

Table 17 shows trends over time in the proportion of unmarried women age 15-24 who are sexually active. The data do not indicate a consistent trend toward greater sexual activity in this population; rather, the proportion reported to be sexually active declines in about as many countries as it

increases. Regarding the denominator for the unmet need indicator (women at risk of pregnancy) among young women, this finding suggests that decreases in the proportion marrying at young ages is not everywhere offset by increases in non- or pre-marital sexual activity among young unmarried women. Changes in the proportion experiencing unmet need among young sexually active, unmarried women is not consistently due to more women moving into this classification.

**Table 16. Percentage sexually active among unmarried women age 15-24, by five-year age group, most recent DHS surveys, 2000-2012**

### 9.2.1 West and Central Africa

In West and Central Africa an average of 18.8 percent of unmarried women age 15-24 report being sexually active; this is the highest level of all the regions (Table 16). Senegal, Mali, and Chad are at the low end of the range, with proportions ranging from 2.0 percent in Senegal to 4.1 percent in Chad; the proportion exceeds 30 percent in Congo Brazzaville (32.1%), Côte d'Ivoire (31.5%), and Gabon (36.3%), and reaches a high of 42.6 percent in Liberia. On average, the proportion of unmarried women age 20-24 who are sexually active (27.9%) is nearly twice that of unmarried women age 15-19 (14.7%). Table 17 shows that the proportion of unmarried women age 15-24 who report being sexually active has decreased in six of the 11 countries with multiple DHS surveys and increased in the remaining five countries.

### 9.2.2 East and Southern Africa

The proportion of unmarried women age 15-24 in East and Southern Africa who report being sexually active averages 9.7 percent, the lowest level of all the regions (Table 16). The proportion ranges from 1.5 percent in Burundi to 25.5 percent in Mozambique. In contrast to West and Central Africa, the majority of countries (eight out of 14) in East and Southern Africa have proportions of sexually active, unmarried women age 15-24 below 10 percent. Comparing unmarried women age 15-19 with those age 20-24, the proportion who are sexually active is substantially higher in the older age group—more than twice as high among unmarried women age 20-24 (17.0%) as among those age 15-19 (6.6%) on average. Table 17 shows that the majority of countries in the region—eight of 11 with multiple DHS surveys—experienced a decline over time in the proportion of unmarried women age 15-24 who report being sexually active. Increases occur in three countries: Ethiopia, Lesotho, and Mozambique.

### **9.2.3 Eastern Europe and Central Asia**

Only three countries in Eastern Europe and Central Asia—Albania, Moldova, and Ukraine—have data on sexual activity among unmarried women age 15-24. The proportion of unmarried women who report being sexually active ranges from 4.5 percent in Albania to 22.0 percent in Ukraine; the average for the three countries is 12.3 percent (Table 16). Comparing the two age groups—unmarried women age 15-19 and age 20-24—the percentage who are sexually active is more than four times higher among unmarried women age 20-24 (24.3%) than among those age 15-19 (5.3%).

### **9.2.4 Latin America and Caribbean**

On average, 12.8 percent of unmarried women age 15-24 in Latin America and the Caribbean are sexually active (Table 16). The range is from 4.9 percent in Nicaragua to 25.2 percent in Colombia. Comparing the two age groups—unmarried women age 15-19 and unmarried women age 20-24—the proportion sexually active is nearly three times higher among those age 20-24 (21.8%) than among those age 15-19 (8.1%). Table 17 shows that in all seven countries that have multiple DHS surveys there is a distinctive pattern of increase over time in the proportion of unmarried women age 15-24 who are sexually active. These changes are sizable in most countries; for example, in Bolivia the proportion of sexually active, unmarried women age 15-24 more than doubles over the 10-year period from 3.0 percent to 7.8 percent. In Peru, the increase over a decade is from 6.3 percent to 11.3 percent.

## **9.3 Fertility Preferences: Ideal Number of Children**

Table 18 presents the distribution of ideal number of children desired among currently married women age 15-24. The data are from the most recent DHS survey in each of the 61 countries included in the study. Table 19 presents trends in ideal number of children desired in the countries with multiple DHS surveys. Tables 23 and 24 present the same information for all unmarried women age 15-24, regardless of whether or not they are sexually active. Detailed disaggregation of the data displayed in tables 21-24 by five-year age group (15-19 and 20-24) can be found in Appendix Table A8 to A11. These tables provide both the percent distribution and, in the last column of each panel, the *mean number of ideal children* for those providing a numeric response.

**Table 18. Ideal number of children among married women age 15-24, most recent DHS surveys, 2000-2012**

Note: <sup>1</sup>Among those providing a numeric response

### 9.3.1 West and Central Africa

The mean ideal number of children reported by married women age 15-24 is *highest* (5.5), on average, in West and Central Africa (Table 18). The mean ranges from 4.1 children in Ghana to 8.4 in Chad and Nigeria. Among married women age 15-24 the number of children desired has declined in seven of the 13 countries with multiple DHS surveys (Table 19). At the same time, ideal number of children increased in five countries, and there was almost no change in Guinea.

The most common response (mode) to the question on ideal number of children among married women age 15-24 in West and Central Africa is *six or more* children (35.0 percent) followed by *four* children (23.3 percent). Comparing the responses of married women age 15-19 with those of married women age 20-24 indicates only a slight difference in the mean ideal number of children (5.6 versus 5.5, respectively) (see Appendix Table A6). West and Central Africa is also the region with the highest level of non-numeric responses, averaging 8.7 percent among married women age 15-24.

The proportion of women giving a non-numeric responses has declined over time in most of the countries in this region (Table 19), in some cases quite precipitously—e.g., from 16.6 percent to 2.9 percent in Burkina Faso. Benin, Côte d'Ivoire, and Mali are exceptions to this trend; in these countries non-numeric responses have increased over time—e.g., from 8.7 percent to 13.3 percent in Mali. Overall, there has been an increase in the proportion of young married women reporting that their ideal number of children is *four* and there has been a decrease in the proportion of young married women reporting that their ideal number of children is *six or more*.

Note: <sup>1</sup>Among those providing a numeric response

<sup>2</sup>Data on this variable were not collected in Moldova

On average, the mean ideal number of children reported by unmarried women age 15-24 in West and Central Africa is substantially lower than that reported by married women of the same age: 4.5 children as compared to 5.5 children (Table 20). Among unmarried women age 15-24 the mean ranges from 2.8 children in São Tomé and Príncipe to 7.5 children in Chad. As with married women, the mean ideal number of children desired by unmarried women age 15-24 has been declining over time in the majority of countries in the region (Table 21). However, the mean for unmarried women (4.5 children) is still the highest for this population among all the regions in this study. Unlike married women, the most common response (mode) to the question about ideal number of children among unmarried women is *four* children (31.2%), not *six or more* children (19.5%).

Note: <sup>1</sup>Among those providing a numeric response

### 9.3.2 East and Southern Africa

In East and Southern Africa, the mean ideal number of children reported by married women age 15-24 averages 3.9, which is substantially lower than the mean reported by this population in West and Central Africa (5.5) but higher than the means of the other four regions (Table 18). The mean for married women age 15-24 in East and Southern Africa ranges from 2.5 children in Swaziland to 5.6 in Eritrea. The most common response is *four* children (29.2 percent), followed by *three* children (20.3 percent). Like the other regions, there are virtually no differences between the two age groups (15-19 and 20-24) (see Appendix Table A6).

The trend toward desiring fewer children is more evident in East and Southern Africa than in West and Central Africa (Table 19). The mean ideal number of children has declined among married women age 15-24 in 10 of 13 countries with data from multiple DHS surveys, as has the proportion of women providing non-numeric responses. The proportion of married women age 15-24 who report their ideal number of children as *three* has increased in nearly every country in the region; the trend is more mixed for women who report their ideal number of children as *four*.

The mean ideal number of children is lower for unmarried women age 15-24 than for married women by a difference of 0.7—3.2 children compared with 3.9 children (Table 20). The means for unmarried women age 15-24 range from 2.0 in Lesotho to 4.1 in Burundi. The mean ideal number of children has declined over time throughout the region, although the pace of the decline has varied (Table 21). In Madagascar, the mean ideal number of children among unmarried women age 15-24 fell from 7.1 to 3.8 children in just over a decade; the decline is more modest in Malawi, from 3.3 to 3.1 children over

a decade. The most common response (mode) of unmarried women age 15-24 to the question about desired number of children is *two* children (28.8%)—and this proportion has generally increased over time—followed closely by *four* children (24.2%) and *three* children (23.2%), each cited by about one-quarter of unmarried women. This distribution suggests that young unmarried women have a smaller ideal family size compared with their married counterparts.

### **9.3.3 Middle East and North Africa**

The mean ideal number of children among married women age 15-24 in the Middle East and North Africa averages 3.1 and ranges from 2.6 in Egypt to 3.9 in Jordan (Table 18). The most common response to the question about desired number of children (mode) is *two* children (38.7 percent), followed by *four* children (25.8 percent). Table 19 indicates that the mean ideal number of children among married women age 15-24 has declined in Jordan and Morocco, while remaining about the same in Egypt. The proportion reporting their ideal number to be *three* children has increased in all three countries.

### **9.3.4 Eastern Europe and Central Asia**

In Eastern Europe and Central Asia the mean ideal number of children among married women age 15-24 averages 2.6 (Table 18). The mean ranges from 2.0 in Ukraine to 3.9 in Kyrgyz Republic. The most common response to the question about desired number of children (mode) is *two* children (54.9 percent), followed by *three* children (21.1 percent). As with the other regions, there is no discernable difference between the responses of married women age 15-19 and those age 20-24 (Appendix Table A6).

In contrast to the other regions, the mean ideal number of children among married women age 15-24 has increased among the three Eastern European countries—Armenia, Kyrgyz Republic, and Turkey—with trends data (Table 19). The largest increase is in the Kyrgyz Republic where the mean ideal number of children increased from 3.5 to 3.9 children. Unlike the other two countries in the region, the most commonly reported ideal number of children among young married women in Kyrgyz Republic remains *four* children. In Armenia and Turkey, the proportion responding that *two* children is their ideal number of children has declined and the proportion stating that *three* children is their ideal has increased over time, although these responses continue to be the first and second most common responses, respectively.

In the two countries supplying data on unmarried women age 15-24, Albania and Ukraine, there is little difference in the mean ideal number of children among *unmarried* women and *married* women age 15-24 (Table 20). In Albania, the mean ideal number of children is 2.3 among unmarried women as compared to 2.5 among married women; in Ukraine, the difference is indistinguishable. As is the case with their married counterparts, the most common response (mode) is that *two* children is the ideal number of children in both countries.

### **9.3.5 South and Southeast Asia**

In South and Southeast Asia the mean ideal number of children among married women age 15-24 averages 2.8 children (Table 18) and ranges from 2.0 children in Bangladesh and Nepal to 4.9 children in Timor-Leste. The most common response given by young married women to the question about ideal number of children (mode) is *two* children (52.4%), similar to married women in Eastern Europe and Central Asia.

Table 19 exhibits a clear trend toward smaller ideal family size over time in the countries in South and Southeast Asia. The mean ideal number of children among married women age 15-24 declined in six of the eight countries with multiple DHS surveys. In contrast, in Vietnam the mean ideal number of children remained steady between 1997 and 2002 at 2.1 children (about replacement level fertility) and in

Pakistan, after 15 years, the mean ideal number of children remains about 3.9 children. The biggest change in this country is the drastic decline in the proportion of women providing non-numeric responses. Over time, the proportion of young married women reporting *two* children as their ideal number of children has increased in seven of the eight countries providing data. The increase is seen even in Pakistan, the only country in the region where *two* children is not the most common response—*four* children (39.2%) is the most common response in Pakistan. The only country with a decline in the proportion of married women age 15-24 reporting *two* children as the ideal number is Vietnam, from 85 percent to 83 percent.

### 9.3.6 Latin America and Caribbean

The *lowest* mean ideal number of children reported by married women age 15-24 is in the Latin America and the Caribbean region, averaging 2.4 children. The region also has the *lowest* proportion of women providing a non-numeric response (0.8 percent) (Table 18). The mean ranges from 2.0 children in Colombia to 2.7 in Dominican Republic. The most common response to the question about ideal number of children (mode) is *two* children (47.8 percent), followed by *three* children (26.7 percent), with no apparent differences between the two age groups (15-19 and 20-24) (Appendix Table A6).

Table 19 reveals that the mean ideal number of children among married women age 15-24 in Latin America and the Caribbean has declined in most countries with multiple DHS surveys. However, it has increased slightly over time in Nicaragua and Peru. In all countries except Peru, the proportion of married women age 15-24 reporting *three* children as their ideal number of children has declined; at the same time, the proportions reporting that their ideal is *two* children or *one* child have increased.

Table 20 shows that there is little difference in the mean ideal number of children reported by married women age 15-24 (2.4 children) and unmarried women age 15-24 (2.3 children) in Latin America and the Caribbean. Among unmarried women, the mean ranges from 1.9 in Colombia to 2.5 in the Dominican Republic. Table 21 shows that, in general, there has been a decrease over time in the mean ideal number of children, except in Nicaragua, where it increased from 2.1 children to 2.3 children. Among unmarried women age 15-24, the most common response (mode) to the question about ideal number of children is *two* children (53.9 percent), followed by *three* children (22.1 percent); the pattern is similar to that of married women age 15-24.

## 9.4 Fertility Preferences: Desired Timing of Next Birth

Table 22 indicates the proportion of married women age 15-24 in three categories of desired timing of next birth, women who: 1) want a child (or another child) within two years, 2) after two or more years, or 3) want no (more) children. These categories correspond roughly, assuming fecundability, to 1) women with no need for family planning, 2) women with need for spacing, and 3) women with need for limiting. Table 23 presents trends in desired timing of next birth for countries with multiple DHS surveys. Data on desired timing of next birth in this population are disaggregated by five-year age group (15-19 and 20-24) in Appendix Table A12 (current levels) and Appendix Table A13 (trends).

Together, Tables 22 and 23 indicate that, on average, most married women age 15-24 in all regions want to postpone a(another) birth for at least two years and that this preference has existed for some time. This finding indicates that the greatest need—met or unmet—among young married women is need for spacing and that this proportion exceeds the proportion with no need for family planning. Having no need for family planning is the second most common need category, on average, in all regions except in Latin America and the Caribbean. Comparing the two age groups of young married women (15-19 and 20-24), very similar proportions in each age group want to postpone a birth for at least years in all regions except South and Southeast Asia and Latin America and the Caribbean (Appendix Table A12). In all

regions except West and central Africa, a higher proportion of married women age 15-19 want a birth within two years and a higher proportion of married women age 20-24 want no (more) births. These proportions are similar across both age groups in West and Central Africa.

Note: Columns may not sum to 100% due to omission of women who are sterilized, infecund, or who are missing data

Data on the current state of desired timing of a subsequent birth for sexually active, unmarried women age 15-24 are presented in Table 24 and trends for this population are presented in Table 25. Appendix Table A14 to A15 provide these data by five-year age group (15-19 and 20-24). These data indicate that a much larger proportion of sexually active, unmarried women age 15-24 want to delay a birth for two or more years, compared with married women the same age. A smaller proportion of sexually active, unmarried women age 15-24 wants a child within two years or wants no (more) children, compared with married women. This pattern is evident in all regions for which data are available on sexually active, unmarried women. Comparing the two age groups, the proportion of women of both age groups who want to delay a birth for two or more years is very similar in West and Central Africa and in Eastern Europe and Central Asia, while a slightly higher percentage of sexually active, unmarried women age 15-19 want a birth within two years and a slightly higher proportion of those age 20-24 want no (more) births (Appendix Table A14). In East and Southern Africa and Latin America and the Caribbean, a higher proportion of those age 15-19 want to delay a birth by two or more years, while both the proportion wanting a birth within two years and the proportion wanting no (more) births are higher among those age 20-24.

#### 9.4.1 West and Central Africa

Countries in West and Central Africa, on average, have the *highest* proportion of married women age 15-24 who want to postpone having a child for two or more years (67.2%) and the *lowest* proportion of married women age 15-24 who want no more children (5.1%) (Table 22). The proportion of women who want a child after two or more years ranges from 55.2 percent in Sierra Leone to 85.1 percent in Congo (Brazzaville). At the same time, more than one-quarter (26.6%) of young married women would like a child within two years; only 5.1 percent want no (more) children. São Tomé and Príncipe stands out in the region because of the small proportion of married women age 15-24 who want a child within two years (6.4%) and the large proportion who want no (more) children (22.9%).

Table 23 demonstrates that, over time, the most frequently occurring trend among married women age 15-24 in West and Central Africa is an *increase* the proportion who want to *delay a birth by two or more years*. There has been a *decrease* in the proportion of married women age 15-24 who want a child *within two years* and a *decrease* in the proportion who *want no (more) children*. While the decline in the proportion of young married women who want a child soon (within two years) is clear, the trend in the proportion wanting no (more) children varies across countries in the region.

Among sexually active, unmarried women age 15-24 in West and Central Africa, the vast majority—85.3 percent, on average—want to delay having a child for two or more years (Table 24). Eastern Europe and Central Asia is the only region with a higher proportion (89.6%). When young unmarried women are compared with young married women in West and Central Africa, there is a difference of nearly 20 percentage points in the proportion wanting a child *after two or more years*—85.3

percent and 62.2 percent, respectively. The proportion of sexually active, unmarried women who want a child *within two years* averages 10.3 percent and ranges from less than one percent in Senegal to more than 20 percent in Cameroon and São Tomé and Príncipe. It is rare for sexually active, unmarried women in this age group to want to have no (more) children. In West and Central Africa the proportion of young unmarried women age who *want no (more) children* ranges from zero percent in Burkina Faso to 7.4 percent in São Tomé and Príncipe. Among the regions, West and Central Africa and Eastern Europe and Central Asia have the lowest proportions of sexually active, unmarried women age 15-24 who want no (more) children—both regions averaging 2.9 percent.

Trends in desire for a(nother) child among sexually active, unmarried women age 15-24 show *an even greater concentration*, compared to married women of the same age, of desires over time to postpone having a child for two or more years, rather than either wanting a child within two years or wanting no (more) children, both proportions that *decrease* over time (Table 25). Exceptions include Ghana, where there is an *increase* in the proportion wanting no more children, and Mali, where there is a *decrease* in both the proportion wanting a child soon (within two years) and the proportion wanting a child later (after two or more years), along with an *increase* in the proportion wanting no (more) children. The desire to have a child within two years declined almost universally among sexually active, unmarried women age 15-24, with the exception of Congo (Brazzaville) where there was a slight increase (from 10.1% to 11.2%).

#### **9.4.2 East and Southern Africa**

Compared with young married women in West and Central Africa, a smaller proportion of married women age 15-24 in East and Southern Africa want to have a child either within two years (20.8%) or after two or more years (62.5%) (Table 22). Although still the least common response to the question about desire for a(nother) child, a larger proportion of young married women in East and Southern Africa than in West and Central Africa want no (more) children (16.3% and 5.1%, respectively). The proportion of married women age 15-24 who want to postpone having a child for two or more years ranges from 40 percent in Namibia (40.1%) and Swaziland (40.4%) to more than 80 percent in Burundi (81.1%). Eritrea and Mozambique contrast with the general pattern, with a high proportion of young married women wanting a child within two years—37.7 percent in Eritrea and 40.8 percent in Mozambique—and, for Eritrea, a small proportion wanting no (more) children (3.4%). In contrast, Lesotho, Namibia, and Swaziland have high proportions of young married women who want no (more) children (35.3%, 41.4%, and 45.4%, respectively).

As in West and Central Africa, Table 23 shows that the general trend over time has been a *decrease* in the proportion of married women age 15-24 who want a child within two years and an *increase* in either or both the proportion wanting to space or limit births; the two exceptions are Eritrea and Mozambique. In Eritrea, an increase in the proportion wanting a birth within two years was accompanied by a decrease in the proportion wanting to have a child after two or more years and a decrease in the proportion wanting no (more) children. In Mozambique, there was an increase in the proportion wanting a birth within two years, accompanied by a decrease in the proportion wanting to delay the next birth two or more years, and an increase in the proportion wanting no (more) children.

Desired timing of next birth among sexually active, unmarried women age 15-24 in East and Southern Africa is similar to that among married women the same age. Typically, they want a child after two or more years rather than either wanting a child soon (within two years) or not wanting any (more) children (Table 24). As in the other regions, a greater proportion of young unmarried women want to delay the next birth while smaller proportions want a child soon or want no (more) children. However, compared with other regions, East and Southern Africa has, on average, the *lowest proportion* of sexually active, unmarried women who want to space the next birth by two or more years and the *highest*

*proportions* who want a child within two years or want no (more) children. The shift over time away from wanting a child within two years to wanting (especially) to postpone the next birth is more evident among young sexually active, unmarried women than it is among their married counterparts (Table 25).

#### **9.4.3 Middle East and North Africa**

The Middle East and North Africa region, on average, has the *highest proportion* of married women age 15-24 who want a child within the next two years (27.8%) (Table 22). This proportion ranges from 27.0 percent in Morocco to 29.1 percent in Jordan. Nonetheless, the majority (58.6%) of young, married women in the region want to delay a subsequent birth for two or more years. This proportion ranges from 53.6 percent in Egypt to 63.0 percent in Jordan. Smaller proportions of young married women report that they want no (more) children, ranging from 7.5 percent in Jordan to 19.1 percent in Egypt. Table 23 shows that both Egypt and Morocco have seen an increase in the proportion of married women age 15-24 who want to postpone having a child for two or more years; trends in the other two categories vary. In Jordan, the proportion of young married women who want to postpone having a child for two or more years and the proportion who want to limit childbearing have both fluctuated over time; however, there has been an *increase* in the proportion who want a child within two years, from 27.5 percent to 29.1 percent.

#### **9.4.4 Eastern Europe and Central Asia**

The proportion of married women age 15-24 in Eastern Europe and Central Asia who want to postpone having a child after two or more years averages 58.6 percent and ranges from 35.8 percent in Azerbaijan to 70.9 percent in the Kyrgyz Republic (Table 22). Nearly one-quarter of married women this age (23.7%) want a child within two years on average, ranging from 18.9 percent in Turkey to 29.1 percent in Azerbaijan. The proportion wanting no (more) children ranges from 1.4 percent in the Kyrgyz Republic to 29.7 in Azerbaijan. Azerbaijan stands out from the other countries in the region because of the relatively smaller proportion of young married women wanting to space the next birth (35.8%) and the larger proportions wanting the next birth soon (29.1%) or not at all (29.7%).

Table 23 shows that for the three countries in Eastern Europe and Central Asia for which multiple DHS surveys are available—Armenia, Kyrgyz Republic, and Turkey—there has been an *increase* in the proportion of married women age 15-24 who want to delay having a child for two or more years and a *decrease* in the proportion who want to have no (more) children. The proportion wanting a child within two years has decreased in Turkey and increased in Armenia and the Kyrgyz Republic.

Among the three countries in the region—Albania, Moldova, and the Ukraine—with data on both married and sexually active, unmarried women age 15-24, Table 24 indicates that, on average, the proportion of young women who want to delay the next birth two or more years is at least 30 percentage points *higher* among sexually active, unmarried women than among their married counterparts—89.6% and 58.6%, respectively. Among the four regions with data on sexually active, unmarried women age 15-24, Eastern Europe and Central Asia has the *highest proportion* of these women who want a child after two or more years. The proportions wanting a child within two years or wanting no (more) children are small, a fraction of those of young married women. In particular, among the four regions with data available, Eastern Europe and Central Asia has the *lowest proportion* of sexually active, unmarried women age 15-24 who want a child within two years (6.9%).

#### **9.4.5 South and Southeast Asia**

Although the majority of married women age 15-24 in South and Southeast Asia want to postpone a (next) birth two or more years (59.9%), on average, the region has the *second highest*

proportion of married women wanting no more children (18.4%) and the *second lowest* proportion wanting a child within two years (19.8%) (Table 22). The proportion who want a (next) birth after two or more years ranges from 39.7 percent in India to 83.0 percent in Timor-Leste. The proportion who want to limit childbearing (i.e., have no (more) children) ranges from 3.3 percent in Timor-Leste to 32.7 percent in Nepal. The proportion who want a child within two years ranges from 10.4 percent in Vietnam to 38.4 percent in Pakistan. India is notable for having relatively similar proportions of women in all three categories. While Nepal and Pakistan have similar proportions of married women age 15-24 who want to delay a (next) birth two or more years (47.7% and 49.6%, respectively), they differ in the large proportion of women in Pakistan who want a birth soon (38.4%) and the large proportion of women in Nepal who want no (more) children (32.7%), and these proportions have increased over time (Table 23). Trends in desired timing of next birth in the other countries in South and Southeast Asia are more diverse, with the majority of countries experiencing an increase in the proportion of married women age 15-24 who want to limit or space births, although these trends have moved in opposite directions in some countries.

#### **9.4.6 Latin America and Caribbean**

The Latin America and the Caribbean region has the *highest proportion* of married women age 15-24 who want no (more) children and the *lowest proportion* who want a child soon or after two or more years (Table 22). On average, 55.7 percent of young, married women want a child after two or more years, ranging from 43.1 percent in Bolivia to 66.2 percent in Haiti. Bolivia is notable in the region for having one of the lowest proportions of young married women who want a child soon (7.8%) along with the highest proportion (48.5%) who want no (more) children.

In five of the seven countries in Latin America and the Caribbean with multiple DHS surveys, the proportion of married women age 15-24 who want a child within two years has *decreased* and the proportion wanting a child after two or more years has *increased* (Table 23). In Nicaragua and Peru, the proportion of young married women wanting to space a (next) birth increased but there is a concurrent increase in the proportion of young married women wanting a child soon (within two years). In Haiti and Peru, the proportion of married women age 15-24 wanting to limit (stop) childbearing has *increased* over time. Elsewhere in the region, the desire to limit childbearing has decreased.

Desired timing of next birth among sexually active, unmarried women age 15-24 in Latin American and Caribbean is similar to that of their married counterparts: most sexually active, unmarried women want to space a (next) birth by two or more years (Table 24). However, there is a 20 percentage point difference between the two groups in the desire to space births. On average, 76.3 percent of sexually active unmarried women age 15-24 want to have a (next) birth after two or more years compared with 55.7 percent of young married women the same age. Smaller proportions of sexually active, unmarried women want to have a child soon (within two years) or to have no (more) children. There is a more than 16 percentage point difference in the opposite direction between the two groups in desire to limit childbearing. On average, 12.4 percent of sexually active, unmarried women age 15-24 want no (more) children compared with 29.2 percent of their married counterparts. Table 25 shows that, in general, there has been an *increase* over time in the proportion of sexually active, unmarried women who want to have a child after two or more years, with smaller proportions wanting a child within two years or wanting no (more) children. It is notable that in Haiti there has been a shift away from wanting a(nother) child—either within two years or after two or more years—toward wanting no (more) children. In Nicaragua, the opposite pattern is seen: there has been an *increase* in the proportion of sexually active, unmarried women age 15-24 who want a child within two years or after two or more years, and a *decrease* in the proportion wanting no (more) children.

## 9.5 Use of Contraception

Table 26 describes current use of contraception among married women age 15-24. Data on current use of contraception among the same population disaggregated by five-year age group (15-19 and 20-24) can be found in Appendix Table A16. These tables present 1) the proportion of women not using any contraceptive method (nonusers), 2) the proportion using a traditional method, and 3) the proportion using a modern method. Although the DHS algorithm for unmet need for family planning considers women using *any* method of contraception to have a *met need* for family planning and not unmet need (Bradley et al. 2012), service providers concerned with the efficacy of contraceptive methods may be interested in the distinction between modern method and traditional method use among young women.

**Table 26. Current use of contraception among married women age 15-24, by method type, most recent DHS surveys, 2000-2012**

<b>Regional average</b>		<b>44.6</b>	<b>7.6</b>	<b>47.8</b>	<b>18,872</b>

Table 26 indicates that most married women age 15-24 are not currently using contraception. Only in Latin America and the Caribbean does a majority—55.4 percent, on average—use a method of contraception. In every other region in this report, the majority of young married women do not use any contraceptive method. When contraception *is* used however, a greater proportion of young married women in all regions use a modern method than a traditional method. Use of *modern methods* by married women age 15-24 is highest in Latin America and the Caribbean (averaging 47.8%), followed by the Middle East and North Africa (where it averages 37.7%). Eastern Europe and Central Asia is distinctive because of the high proportion of young married women using *traditional methods* (22.5%), almost the same proportion of young married women are using modern methods (23.5%). In other regions the proportion of young married women using traditional methods is less than 10 percent. In all regions, use of contraception is higher among married women age 20-24 than among those age 15-19, but the distribution of modern and traditional methods is similar in both age groups (Appendix Table A16).

Table 27 provides trend data on current use of contraception among married women age 15-24 in countries with multiple DHS surveys. These data are presented for the two constituent five-year age groups (15-19 and 20-24) in Appendix Table A17. Table 27 demonstrates *a strong and nearly universal trend toward increased use of modern contraceptive methods*. At the same time, however, there is variation as to whether the *increase* in the use of modern methods is accompanied by 1) a *decrease* in nonuse of contraception and an *increase* in the use of traditional methods, or 2) an *increase* in nonuse of contraception and a *decrease* in the use of traditional methods, or 3) a *decrease* in both nonuse of contraception and use of traditional methods. Generally, trends in current use of contraception do not differ by age group (Appendix Table A17).

Table 28 presents current use of contraception among sexually active, unmarried women age 15-24, by method type, for countries with DHS data on unmarried women. Appendix Table A18 provides corresponding data by five-year age group. Table 28 indicates that, compared with married women age 15-24 a greater proportion of sexually active, unmarried women age 15-24, in all regions, are currently using a contraceptive method. Still, the majority of young unmarried women in both African regions (West and Central Africa and East and Southern Africa) do not use any method of contraception. Use of modern methods among this population is highest in Latin America and the Caribbean (56.0%), followed closely by Eastern Europe and Central Asia (54.5%). Use of traditional methods is higher among sexually active, unmarried women age 15-24, on average, than it is among their married counterparts. Again, use of traditional methods is highest in Eastern Europe and Central Asia (25.5%), although more than twice as many young unmarried women in this region use modern methods (54.5%). As with young married women, a higher proportion of sexually active, unmarried women age 20-24 use a method of contraception as compared to their counterparts age 15-19, except in Eastern Europe and Central Asia where there are no differences by age (Appendix Table A18).

Table 29 displays the trends in current use of contraception among unmarried women age 15-24 for countries with multiple DHS surveys that include this population, with corresponding data by five-year age group provided in Appendix Table A19. As with married women age 15-24 there is strong trend toward *increased* use of modern methods of contraception. The concurrent trends in nonuse of contraception and use of traditional methods are as varied among young unmarried women as they are among young married women.

### 9.5.1 West and Central Africa

Among married women age 15-24, West and Central Africa has the *lowest level* of use of contraception—15.6 percent. Conversely, 84.4 percent of young married women are not using any method of contraception (Table 26). Nonuse of contraception ranges from 56.8 percent in Congo (Brazzaville) to 95.8 percent in Sierra Leone. Use of modern methods (10.2%) is nearly double that of traditional methods (5.4%). The differential in use of traditional versus modern methods is perhaps greatest in São Tomé and Príncipe where 1.8 percent of young married women use traditional methods and 32.4 percent use modern methods. Notably, this level of use of modern methods in São Tomé and Príncipe is the highest for the region. The pattern is reversed in Chad and Niger, where a greater proportion of young married women use traditional methods than use modern methods.

In all the countries for which trend data are available use of modern methods among married women age 15-24 has *increased* over time (Table 27). In eight of 13 countries, this increase has been accompanied by a *decrease* in both nonuse of contraception and use of traditional methods. However, in Benin, Congo (Brazzaville), and Gabon, nonuse of contraception has increased along with use of modern methods, while use of traditional methods has decreased. In Chad and Niger, use of both traditional and modern methods has increased while the proportion not using any method has decreased.

Table 28 shows that, compared with married women age 15-24, a smaller proportion of sexually active, unmarried women age 15-24 are not using contraception (84.4% and 53.4%, respectively). The proportion of nonusers among young sexually active, unmarried women ranges from 24.3 percent in Congo (Brazzaville) to 90.2 percent in Chad. Use of modern methods, which averages 35.0 percent among young unmarried women, is more than triple the level among young married women. The percentage of sexually active, unmarried women age 15-24 who use a modern method of contraception

ranges from 9.8 percent in Chad to 57.6 percent in Burkina Faso. Use of traditional methods in this region is higher than in either East and Southern Africa or Latin America and the Caribbean. Use of traditional methods averages 11.6 percent among sexually active, unmarried women age 15-24, ranging from zero use in Chad to 28.9 percent in Benin.

Trends in current use of contraception among sexually active, unmarried women age 15-24, presented in Table 29, indicate that use of modern methods has generally *increased* in this population just as it has among young married women with one exception, Mali. At the same time, use of traditional methods has *decreased* over time in every country in the West and Central Africa region. The proportion of sexually active, unmarried women age 15-24 not using any contraceptive method has *increased* in seven of 11 countries and *decreased* in the remaining four countries: Benin, Burkina Faso, Ghana, and Nigeria.

### 9.5.2 East and Southern Africa

More than two-thirds (67.4%) of married women age 15-24 in East and Southern Africa, on average, are not using any method of contraception; only West and Central Africa has a higher proportion of nonusers (Table 26). The proportion not using any method in East and Southern Africa ranges from 46.3 percent in Zimbabwe to 95.5 percent in Eritrea. These two countries, respectively, have the *highest* proportion (52.6%) and the *lowest* proportion (3.8%) of young married women using a modern method. At the same time, use of modern methods exceeds use of traditional methods in all of the countries in the region. Averaging just 3.1 percent, East and Southern Africa has the *lowest* proportion of married women age 15-24 using traditional methods.

As in other regions, use of modern methods by married women age 15-24 has generally *increased* over time (Table 27). Among the countries in East and Southern Africa with multiple DHS surveys, all show an *increase* over time in the use of modern methods, with the exception of Eritrea. This trend has been accompanied by a *decrease* in the proportion of young married women not using any method of contraception. (In Eritrea, the proportion of young married women not using contraception actually *increased* from 92.9 percent in 1995 to 95.5 percent in 2002.) Use of traditional methods among young married women has *decreased* alongside the *decrease* in the proportion not using any method of contraception and the *increase* in the use of modern methods—with the exception of Malawi, where use of traditional methods has increased modestly.

Among sexually active, unmarried women age 15-24, East and Southern Africa averages the *highest* levels of nonuse of contraception (53.7%) (Table 28). The proportion not using any method of contraception is nonetheless lower among young unmarried women than it is among young married women. Nonuse of contraception is lowest in Namibia (22.8%) and highest in Burundi (83.3%). Use of modern methods by sexually active, unmarried women in East and Southern Africa averages 42.7 percent. Use of traditional methods is generally low—as it is among young married women—averaging 3.6 percent. Madagascar stands out in the region because 17.4 percent of sexually active, unmarried women age 15-24 in that country use traditional methods. Elsewhere in the region the proportion using traditional methods is less than 10 percent.

Over time, the general trend among sexually active, unmarried women age 15-24 has been an *increase* in the use of modern methods accompanied by a *decrease* in both nonuse of contraception and use of traditional methods (Table 29). The reverse trend occurs in Uganda. In Tanzania, there has been an *increase* in the use of both traditional and modern methods.

### 9.5.3 Middle East and North Africa

In the Middle East and North Africa, the proportion of married women age 15-24 who are not using any method of contraception averages 55.5 percent and ranges from 46.8 percent in Morocco to 60.3 percent in Jordan (Table 26). The level of nonuse in Egypt (59.5%) is similar to that in Morocco. Use of modern methods is *higher*, on average, in the Middle East and North Africa than in any other region except Latin America and the Caribbean, ranging from 27.8 percent in Jordan to 48.6 percent in Morocco. Only in Jordan does use of traditional methods exceed 10 percent of married women age 15-24. This proportion is less than five percent in Egypt and Morocco.

Table 27 indicates that use of modern methods has *increased* in this population over time and the proportion of women not using any method of contraception has *decreased*. In Egypt and Morocco these changes have been accompanied by an *increase* in the use of traditional methods—although the proportions are still relatively low. In Jordan, use of traditional methods has fluctuated over time.

### 9.5.4 Eastern Europe and Central Asia

After Latin America and the Caribbean, Eastern Europe and Central Asia has the lowest proportion of married women age 15-24 who are not using contraception (Table 26). On average, 54.0 percent of young married women in Eastern Europe and Central Asia are not using any contraceptive method, ranging from 37.7 percent in Moldova to 80.7 percent in Azerbaijan. At the same time, use of modern methods is quite low. Less than one-quarter (23.5%) of young married women use modern methods, ranging from 8.2 percent in Azerbaijan to 40.1 percent in Moldova. In contrast, the region has the *highest level* of use of traditional methods. The Kyrgyz Republic is the exception in the region, with only 1.9 percent of married women age 15-24 using traditional methods. The average is 22.5 percent, with a high of 43.8 percent of young married women use traditional methods in Albania.

The three countries in Eastern Europe and Central Asia for which multiple DHS surveys are available—Armenia, the Kyrgyz Republic, and Turkey—displays a different trend in use of contraception over time compared to the other regions in this report (Table 27). In Armenia and the Kyrgyz Republic, use of contraceptive methods, either traditional or modern, has declined over time while nonuse of contraception has increased. Only in Turkey has use of contraception increased. In this country, increases are seen in use of both modern and traditional methods, although use of traditional methods outpaces use of modern methods.

Eastern Europe and Central Asia has the *lowest proportion* of sexually active, unmarried women age 15-24 not using any method of contraception (Table 28). This proportion, which averages 20.0 percent for the three countries in the region with DHS data on this population, is less than half that among young married women, and ranges from 9.6 percent in the Ukraine to 27.7 percent in Moldova. Correspondingly, use of both modern methods (54.5%) and traditional methods (25.5%) is *high* relative to the other regions and exceeds use among young married women. Use of traditional methods is highest in Albania, at 48.4 percent, and relatively low in Ukraine (3.8 percent).

### 9.5.5 South and Southeast Asia

On average, nearly 65 percent of married women age 15-24 in South and Southeast Asia are not using contraception, while more than 35 percent are using a contraceptive method of some kind. Use of modern methods is fourfold that of traditional methods (28.5% and 6.6%, respectively) (Table 26). However, there is substantial variation within the region. Nonuse of contraception is lowest in Indonesia (41.8 percent) and highest in Pakistan (87 percent). Use of a modern methods averages 28.5 percent, but ranges from 8.8 percent in Pakistan to 57 percent in Indonesia. Use of traditional methods is lowest in

Timor-Leste and Indonesia (both 1.1%), but exceeds 10 percent in Cambodia, Vietnam, and the Philippines.

Throughout the region, use of modern methods has *increased* and nonuse of contraception has *decreased* among married women age 15-24 over time (Table 27). Use of traditional methods has increased in five of the eight countries with trends data but has decreased in Bangladesh, Indonesia, and the Philippines.

### **9.5.6 Latin America and Caribbean**

Latin America and the Caribbean has, on average, the *highest level* of use of modern methods and the *lowest level* of nonuse of contraception among married women age 15-24 (Table 26). Use of modern methods, which averages 47.7 percent, is highest in Colombia (62.6%) and lowest in Bolivia (33.0%) and Haiti (31.6%). The proportion of young married women not using any method of contraception is 44.6 percent, ranging from 29.9 percent in Peru to 66.6 percent in Haiti. Latin America and the Caribbean has relatively high levels of use of traditional methods, with an average of 7.6 percent of young married women using these methods. Use of traditional methods is uncharacteristically high in Bolivia and Peru, exceeding 19 percent in these countries.

Trends in use of contraception among married women age 15-24 in Latin America and the Caribbean reflect the broader global trends (Table 27). The proportion of young married women using a modern method of contraception has *increased* while the proportion not using any method has *decreased*. The change has been especially large in Bolivia, the Dominican Republic, and Nicaragua, countries in which nonuse of contraception has decline by at least 12 percentage points over a period of about 10 years. In most countries, use of traditional methods has *decreased* as use of modern methods has increased and nonuse of contraception has decreased. However, the proportion using traditional methods increased in Honduras and Peru and remains unchanged in Nicaragua.

Latin America and the Caribbean also has the *highest level* of use of modern methods among sexually active, unmarried women age 15-24 (Table 28). This proportion, which averages 56.0 percent, ranges from 32.7 percent in Haiti to 74.9 percent in Colombia. As with other regions, these levels of use of modern methods are higher among young unmarried women than they are among young married women. The proportion not using any method of contraception averages 32.5 percent among sexually active, unmarried women age 15-24 and ranges from 12.1 percent in Peru to 64.9 percent in Haiti. Use of traditional methods in Latin America and the Caribbean is *low* relative to the other regions, averaging 11.5 percent among young unmarried women; however, there is considerable variation within the region. Only 2.5 percent of sexually active, unmarried women age 15-24 use traditional methods in Haiti—where overall use of contraception is low—but this proportion rises to 21.7 percent in Peru and to 31.2 percent in Bolivia.

While use of modern methods has demonstrably *increased* over time among sexually active unmarried women age 15-24 in Latin America and the Caribbean (Table 29), the trends in nonuse of contraception and in use of traditional methods are more varied. Nonuse of contraception among young unmarried women has *declined* in five of the seven countries with trend data available, but *increased* in Colombia and Haiti. Use of traditional methods has *increased* in Bolivia and Honduras—along with an increase in the use of modern methods—but decreased elsewhere. Thus, in the Dominican Republic, Nicaragua, and Peru there has been a shift away from nonuse of contraception and use of traditional methods toward increased use of modern methods.

## 10 Limitations

This study focuses specifically on the youth population in 61 low and middle income countries. It covers a wide range of topics related to unmet need in this population and applies a consistent measure by which to compare levels of unmet need across countries and over time. Although this study counts these attributes among its strengths, it also has several limitations that deserve mention.

First, the DHS Program does not have global coverage of survey data for all countries. This is especially the case for data on never married women. Averages of countries within the regions described in this study should not be mistaken for overall regional averages due to this lack of complete coverage. Second, the study is descriptive in nature. Although several factors are revealed to be associated with levels of unmet need among young married women, no causality can be attributed to these factors. Furthermore, these associations are identified through bivariate analyses so a spurious relationship cannot be ruled out. Finally, the estimates of unmet need among unmarried women rely on respondents accurately and truthfully reporting recent sexual activity. Recall errors regarding the timing of most recent sexual intercourse and social desirability bias surrounding sexual activity outside of marriage may yield misreporting of “sexually active” status and thus result in an underestimate of unmet need in this population.

## 11 Conclusions

Renewed attention is being paid to *unmet need for family planning*, catalyzed in part by FP2020's initiative to increase investment in family planning services (Carr et al. 2012; FP2020 2013). Young people are a core focus of this initiative, as evidenced by the prominent youth contingent at FP2020 activities (FP2020 2013). This study is the first publication of DHS data specifically focused on young women age 15-24 that uses the recently revised algorithm for unmet need for family planning. The estimates produced are comparable across countries and over time. The following are among this study's key findings.

Among the six regions in this study, unmet need for family planning among married women age 15-24 is highest in the West and Central Africa region (29.3%). Among individual countries, unmet need is highest among young married women in Ghana (45.7%) and Haiti (44.8%) and lowest in Indonesia (8.0%) and Egypt (8.8%). Unmet need for family planning in this population is predominantly unmet need for spacing.

Total demand for family planning (unmet need plus current use of contraception) among young married women is highest in Latin America and the Caribbean (79.9 percent) and lowest in West and Central Africa (45 percent). On average, only slightly more than half (53.4 percent) of this demand is satisfied among study countries.

Unmet need among sexually active, unmarried women age 15-24 is highest in the two African regions, at around 40 percent—West and Central Africa (41.7%) and East and Southern Africa (39.8%). Among individual countries, it is highest in Senegal (69.5%) and lowest in Ukraine (7.3%).

Total demand for family planning among sexually active, unmarried women age 15-24 is consistently high, about 90 percent in all regions. The vast majority of young sexually active, unmarried women simply do not want to become pregnant at the present time. What varies is the proportion of demand for family planning that is satisfied, which ranges from 51.9 percent in West and Central Africa to 83.8 percent in Eastern Europe and Central Asia.

Over time, unmet need among married women age 15-24 has *declined* in the majority of countries—51 of the 61 countries included in the study. West and Central Africa is an exception: six of the 10 countries in which unmet need has *increased* are in this region. Increases in current use of contraception among married women age 15-24 have kept pace with or exceeded increases in total demand for family planning. As a result, the proportion of demand for family planning satisfied has generally increased over time.

Trends in unmet need among sexually active, unmarried women age 15-24 are less consistently encouraging than the trends seen among young married women. Unmet need among young unmarried women has decreased in about half the countries in the study but increased or fluctuated over time in the remaining countries. In particular, unmet need among sexually active, unmarried women age 15-24 has increased in the majority of countries in West and Central Africa. Demand for family planning has remained steady, and relatively high, over time.

It is estimated that nearly 33 million women age 15-24 have an unmet need for family planning in the 61 countries included in the study. This figure means that more than one-quarter of FP2020's goal to provide services to 120 million new users by 2020 could be achieved by meeting the needs of these young women in these countries (FP2020 2013). Approximately two-thirds of the 33 million young women with unmet need live in one of the 10 Asian countries in the study. The remaining one-third are distributed throughout the 51 other countries.

A greater *number* of married women age 15-24 have an unmet need for family planning than sexually active, unmarried women age 15-24, both overall and in those countries with data on both married and unmarried women. This pattern is seen despite the larger *percentage* of sexually active, unmarried women experiencing unmet need. It reflects the relatively large proportion of women age 15-24 who are married or in union, compared with women who are unmarried and sexually active. Comparing the two age groups (15-19 and 20-24), on average, more women age 20-24 have an unmet need for family planning than women age 15-19.

Among young married women, unmet need is highest at the youngest ages (women age 15-16), declining with increasing age in most of the regions in the study: East and Southern Africa, Eastern Europe and Central Asia, South and Southeast Asia, and Latin America and the Caribbean. Unmet need increases with age in the Middle East and North Africa; and in West and Central Africa, unmet need peaks among married women age 19-20.

Married women age 15-24 have greater unmet need than married women age 25 and older, in all regions except the Middle East and North Africa. The biggest gap in unmet need between younger women (age 15-24) and older women (age 25+) occurs in Latin America and the Caribbean, where unmet need among married women age 15-24 is, on average, more than six percentage points higher than among married women age 25-49. However, levels of unmet need are generally similar for younger and older women in the Middle East and North Africa, albeit with unmet need being less than two percentage points higher among *older* married women (age 25-49) than younger married women (age 15-24).

Place of residence (urban or rural) is a significant factor in unmet need among married women age 15-24 in 25 of 61 countries and, for sexually active, unmarried women of the same age, in 14 of 41 countries. Unmet need is usually *higher* in rural areas for both married and unmarried women. Young women in rural areas are most disadvantaged regarding unmet need in Africa and in Latin America and the Caribbean. In Eastern Europe, urban unmarried women age 15-24 are relatively disadvantaged.

Unmet need among young married women varies significantly by household wealth quintile in 23 of the 61 countries. Generally, unmet need *decreases* with increasing wealth quintile. In West and Central Africa, however, unmet need is also high among women in the highest (richest) wealth quintile.

Educational attainment is associated with unmet need for family planning among married women age 15-24 in most regions and, significantly, in 32 of the 61 countries. The patterns are diverse: unmet need decreases with increasing level of education in the Middle East and North Africa, Eastern Europe and Central Asia, South and Southeast Asia, and Latin America and the Caribbean. In Africa, however, unmet need increases with educational attainment in many countries.

Unmet need among married women age 15-24 varies significantly with parity in 39 of the 61 countries, making it the factor most frequently associated with unmet need of those included in this study. Unmet need increases demonstrably with parity. Differences in unmet need are largest between young married *women with no children* and those *with one child*. In two Latin American countries, Colombia and Peru, nulliparous women have significantly higher unmet need than women with children.

The proportion of women who are married by age 15 or by age 18 is highest in West and Central Africa and lowest in the Middle East and North Africa and Eastern Europe and Central Asia. The general trend is toward delaying marriage, with the proportion marrying by age 15 or by age 18 declining over time. Possible exceptions to this trend exist in Latin America and the Caribbean and East and Southern Africa.

The proportion of unmarried women age 15-24 who report that they are sexually active is highest in West and Central Africa (18.8%) and lowest in East and Southern Africa (9.7%). The data do not

indicate a consistent trend over time; rather, the proportion of sexually active, unmarried women age 15-24 declines in nearly as many countries as it increases (14 and 15 countries, respectively). It does increase, however, in all seven Latin America and Caribbean countries that provided data on this population.

The mean ideal number of children among married women age 15-24 is highest in West and Central Africa (5.5 children) and lowest in Latin America and the Caribbean (2.4 children). It has increased in Eastern Europe and Central Asia (and in selected countries in West and Central Africa) but decreased elsewhere, most notably in South and Southeast Asia. Mean ideal number of children has declined over time among unmarried young women age 15-24. The mean ideal number of children is smaller among unmarried women age 15-24 in Africa and in Eastern Europe and Central Asia as compared to married women of the same age. At the same time, there is almost no difference between young unmarried women and married women in the ideal number of children in Latin America and the Caribbean (unmarried women: 2.3 children; married women: 2.4 children).

Most married women age 15-24 want to postpone a (next) birth for two or more years; the range is from 55.7 percent in Latin America and the Caribbean to 67.2 percent in West and Central Africa. This preference has existed for some time and has become even more normative over time. A much larger proportion of sexually active, unmarried women age 15-24 want to postpone a (next) birth for two or more years than do married women the same age, in just about every country. The range is from 69.1 percent in East and Southern Africa to 89.6 percent in Eastern Europe and Central Asia. As with young married women, the preference to wait two or more years for a (next) birth has become stronger over time among young unmarried women.

Most married women age 15-24 do not use any contraceptive method. In all regions, less than 50 percent of married women are currently using contraception, except in Latin America and the Caribbean, where use of contraception is 55.4 percent among married women age 15-24. Use of modern methods of contraception exceeds use of traditional methods, although use of traditional methods is relatively high in Eastern Europe and Central Asia. A higher proportion of sexually active, unmarried women age 15-24 use contraception compared with their married counterparts. However, the majority of women age 15-24 in both Africa regions do not use any method of contraception. Use of modern methods has increased over time among both married women age 15-24 and sexually active, unmarried women age 15-24.

Overall, unmet need for family planning has declined over time among young women age 15-24 in many countries—especially among young married women. However, levels of unmet need remain substantial in West and Central Africa. In general, sexually active, unmarried women age 15-24 want to avoid a pregnancy to a greater degree than do married women. Unmet need is generally higher among unmarried women than married women, and higher among younger women (age 15-19) than older women (age 20-24).
